CMatching-package

Matching Algorithms for Causal Inference with Clustered Data

# **Description**

Provides functions to perform matching algorithms for causal inference with clustered data, as described in B. Arpino and M. Cannas (2016) <doi:10.1002/sim.6880>. Pure within-cluster and preferential within-cluster matching are implemented. Both algorithms provide causal estimates with cluster-adjusted estimates of standard errors.

### **Details**

Package: CMatching Type: Package Version: 2.3.0 Date: 2019-02-05

License: GPL version 3 or later

Several strategies have been suggested for adapting propensity score matching to clustered data. Depending on researcher's belief about the strength of unobserved cluster level covariates it is possible to take into account clustering either in the estimation of the propensity score model (through the inclusion of fixed or random effects, e.g. Arpino and Mealli (2011)) and/or in the implementation of the matching algorithm (see, e.g. Rickles and Seltzer (2014); Arpino and Cannas (2016)). This package contains main function CMatch to adapt classic matching algorithms for causal inference to clustered data and a customized summary function to analyze the output. Depending on the type argument function CMatch calls either MatchW implementing a pure within-cluster matching or MatchPW implementing an approach which can be called "preferential" within-cluster matching. This approach first looks for matchable units within the same cluster and - if no match is found continues the search in the remaining clusters. The functions also provide causal estimands with cluster-adjusted standard errors from fitting a multilevel model on matched data. CMatch returns an object of class "CMatch" which can be be summarized and used as input of the CMatchBalance function to examine how much the procedure resulted in improved covariate balance. Although CMatch has been designed for dealing with clustered data, these algorithms can be used to force a perfect balance or to improve the balance of categorical variables, respectively. In this case, the "clusters" correspond to the levels of the categorical variable(s). When used for this purpouse the user should ignore the standard error (if provided). Note that Matchby from package Matching can be used for the same purpouse.

CMatch

Within and preferential-within cluster matching.

# Description

This function implements multivariate and propensity score matching in clusters defined by the Group variable. It returns an object of class "CMatch" which can be be summarized and used as input of the CMatchBalance function to examine how much the procedure resulted in improved covariate balance.

# Usage

```
CMatch(type, Y = NULL, Tr, X, Group = NULL, estimand = "ATT", M = 1,
exact = NULL, caliper = 0.25, weights = NULL, replace = TRUE, ties = TRUE, ...)
```

# **Arguments**

type	The type of matching desired. "within" for a pure within-cluster matching and "pwithin" for matching preferentially within. The preferential approach first searches for matchable units within the same cluster. If no match was found the algorithm searches in other clusters.
Υ	A vector containing the outcome of interest.
Tr	A vector indicating the treated and control units.
X	A matrix of covariates we wish to match on. This matrix should contain all confounders or the propensity score or a combination of both.
Group	A vector describing the clustering structure (typically the cluster ID). This can be any numeric vector of the same length of Tr and X containing integer numbers in ascending order otherwise an error message will be returned. Default is NULL, however if Group is missing, NULL or it contains only one value the output of the Match function is returned with a warning.
estimand	The causal estimand desired, one of "ATE", "ATT" and "ATC", which stand for Average Treatment Effect, Average Treatment effect on the Treated and on the Controls, respectively. Default is "ATT".
М	The number of matches which are sought for each unit. Default is 1 ("one-to-one matching").
exact	An indicator for whether exact matching on the variables contained in X is desired. Default is FALSE. This option has precedence over the caliper option.
caliper	A maximum allowed distance for matching units. Units for which no match was found within caliper distance are discarded. Default is 0.25. The caliper is interpreted in standard deviation units of the <i>unclustered</i> data for each variable. For example, if caliper=0.25 all matches at distance bigger than 0.25 times the standard deviation for any of the variables in X are discarded.

weights A vector of specific observation weights.

replace Matching can be with or without replacement depending on whether matches

can be re-used or not. Default is TRUE.

ties An indicator for dealing with multiple matches. If more than M matches are

found for each unit the additional matches are a) wholly retained with equal weights if ties=TRUE; b) a random one is chosen if ties=FALSE. Default is

TRUE.

... Additional arguments to be passed to the Match function (not all of them can be

used).

### Details

This function is meant to be a natural extension of the Match function to clustered data. It retains the main arguments of Match but it has additional output showing matching results cluster by cluster. It differs from wrapper Matchby in package Matching in the way standard errors are calculated and because the caliper is in standard deviation units of the covariates on the overall dataset (so the caliper is the same for all clusters). Moreover, observation weights are available.

### Value

index.control The index of control observations in the matched dataset.

index.treated The index of control observations in the matched dataset.

index.dropped The index of dropped observations due to the exact or caliper option. Note that

these observations are treated if estimand is "ATT", controls if "ATC".

est The causal estimate. This is provided only if Y is not null. If estimand is "ATT"

it is the (weighted) mean of Y in matched treated units minus the (weighted) mean of Y in matched controls. Equivalently, it is the weighted average of the within-cluster ATTs, with weights given by cluster sizes in the matched dataset.

se A model-based standard error for the causal estimand. This is a cluster robust

estimator of the standard error for the linear model: Y ~ constant+Tr, run on the matched dataset (see cluster.vcov for details on how this estimator is obtained). Note that these standard errors differ from a weighted average of cluster specific standard errors provided by the Matchby function, which are generally larger. Estimating standard errors for causal parameters with clustered

data is an active field of research and there is no perfect solution to date.

mdata A list containing the matched datasets produced by CMatch. Three datasets are

included in this list: Y, Tr and X. The matched dataset for Group can be recovered

by rbind(Group[index.treated],Group[index.control]).

orig.treated.nobs.by.group

The original number of treated observations by group in the dataset.

orig.control.nobs.by.group

The original number of control observations by group in the dataset.

orig.dropped.nobs.by.group

The number of dropped observations by group after within cluster matching.

orig.nobs The original number of observations in the dataset.

orig. wnobs The original number of weighted observations in the dataset.

orig.treated.nobs

The original number of treated observations in the dataset.

orig.control.nobs

The original number of control observations in the dataset.

wnobs the number of weighted observations in the matched dataset.

caliper The caliper used.

intcaliper The internal caliper used.

exact The value of the exact argument.

ndrops.matches The number of matches dropped either because of the caliper or exact option (or

because of forcing the match within-clusters).

estimand The estimand required.

### Note

The function returns an object of class CMatch. The CMatchBalance function can be used to examine the covariate balance before and after matching (see the examples below).

# this is equivalent to run Match with X=eps
```

CMatchBalance

Analyze covariate balance before and after matching.

### **Description**

Generic function for analyzing covariate balance. If match.out is NULL only balance statistics for the unmatched data are returned otherwise both before and after matching balance are given. The CMatchBalance 9

function is simply a wrapper calling MatchBalance, possibly after coercing the class of match.out. See MatchBalance for more detailed description.

# Usage

```
CMatchBalance(match.out, formula, data = NULL, ks = TRUE, nboots = 500, weights = NULL, digits = 5, paired = TRUE, print.level = 1)
```

# Arguments

match.out	A matched data set, i.e., the result of a call to Match or CMatch.		
formula	This formula does not estimate a model. It is a compact way to describe which variables should be compared between the treated and control group. See MatchBalance.		
data	An optional data set for the variables indicated in the formula argument.		
ks	A flag for whether Kolmogorov-Smirnov tests should be calculated.		
weights	A vector of observation-specific weights.		
nboots	The number of bootstrap replication to be used.		
digits	The number of digits to be displayed in the output		
paired	A flag for whether a paired t.test should be used for the matched data. An unpaired t.test is always used for unmatched data.		
print.level	The amount of printing, taking values 0 (no printing), 1(summary) and 2 (dtailed results). Default to 1.		

### **Details**

The function is a wrapper of the MatchBalance function. If match.out is of class Match (or NULL) then it calls MatchBalance. If match.out is of classCMatch then it coerces the class to Match before calling MatchBalance. This function is meant to exploit MatchBalance for CMatch objects for which MatchBalance would not work.

# Value

Balance statistics for the covariates specified in the *right* side of formula argument. Statistics are compared between the two groups specified by the binary variable in the *left* side of formula.

```

MatchPW

Preferential Within-cluster Matching

# **Description**

This function implements preferential within-cluster matching. In other words, units that do not match within clusters (as defined by the Group variable) can match between cluster in the second step.

# Usage

```
MatchPW(Y = NULL, Tr, X, Group = NULL, estimand = "ATT", M = 1,
  exact = NULL, caliper = 0.25, replace = TRUE, ties = TRUE, weights = NULL, ...)
```

# **Arguments**

rguments			
Υ	A vector containing the outcome of interest.		
Tr	A vector indicating the treated and control units.		
X	A matrix of covariates we wish to match on. This matrix should contain all confounders or the propensity score or a combination of both.		
Group	A vector describing the clustering structure (typically the cluster ID). This can be any numeric vector of the same length of Tr and X containing integer numbers in ascending order otherwise an error message will be returned. Default is NULL, however if Group is missing, NULL or contains only one value the output of the <i>Match</i> function is returned with a warning.		
estimand	The causal estimand desired, one of "ATE", "ATT" and "ATC", which stand for Average Treatment Effect, Average Treatment effect on the Treated and on the Controls, respectively. Default is "ATT".		
М	The number of matches which are sought for each unit. Default is 1 ("one-to-one matching").		
exact	An indicator for whether exact matching on the variables contained in X is desired. Default is FALSE. This option has precedence over the caliper option.		
caliper	A maximum allowed distance for matching units. Units for which no match was found within caliper distance are discarded. Default is 0.25. The caliper is interpreted in standard deviation units of the <i>unclustered</i> data for each variable. For example, if caliper=0.25 all matches at distance bigger than 0.25 times the standard deviation for any of the variables in X are discarded. The caliper is used for both within and between clusters matching.		

replace Default is TRUE. From version 2.3 this parameter can be set to FALSE. Assum-

ing ATT this means that controls matched within cannot be matched between (i.e. in the second step). However note that, even when replace is set to FALSE,

controls can be re-used during match between.

ties An indicator for dealing with multiple matches. If more than M matches are

found for each unit the additional matches are a) wholly retained with equal weights if ties=TRUE; b) a random one is chosen if ties=FALSE. Default is

TRUE.

weights A vector of observation specific weights.

.. Please note that all additional arguments of the Match function are not used.

### **Details**

The function performs preferential within-cluster matching in the clusters defined by the variable Group. In the first phase matching within clusters is performed (see MatchW) and in the second the unmatched treated (or controls if estimand="ATC") are matched with all controls (treated) units. This can be helpful to avoid dropping many units in small clusters.

### Value

index.control The index of control observations in the matched dataset.

index.treated The index of control observations in the matched dataset.

index.dropped The index of dropped observations due to the exact or caliper option. Note that

these observations are treated if estimand is "ATT", controls if "ATC".

est The causal estimate. This is provided only if Y is not null. If estimand is "ATT"

it is the (weighted) mean of Y in matched treated minus the (weighted) mean of Y in matched controls. Equivalently it is the weighted average of the within-cluster

ATTs, with weights given by cluster sizes in the matched dataset.

se A model-based standard error for the causal estimand. This is a cluster robust

estimator of the standard error for the linear model: y ~ constant+Tr, run on the matched dataset (see cluster.vcov for details on how this estimator is

obtained).

mdata A list containing the matched datasets produced by MatchPW. Three datasets are

included in this list: Y, Tr and X. The matched dataset for Group can be recovered

by rbind(Group[index.treated],Group[index.control]).

orig.treated.nobs.by.group

The original number of treated observations by group in the dataset.

orig.control.nobs.by.group

The original number of control observations by group in the dataset.

orig.dropped.nobs.by.group

The number of dropped observations by group after within cluster matching.

orig.dropped.nobs.by.group.after.pref.within

The number of dropped observations by group after preferential within group

matching.

orig.nobs The original number of observations in the dataset.

orig. wnobs The original number of weighted observations in the dataset.

orig.treated.nobs

The original number of treated observations in the dataset.

orig.control.nobs

The original number of control observations in the dataset.

wnobs the number of weighted observations in the matched dataset.

caliper The caliper used.

intcaliper The internal caliper used.

exact The value of the exact argument.

ndrops.matches The number of matches dropped either because of the caliper or exact option.

estimand The estimand required.

# Note

The function returns an object of class CMatch. The CMatchBalance function can be used to examine the covariate balance before and after matching. See the examples below.

MatchW

Within-cluster Matching

# Description

This function implements multivariate and propensity score matching within clusters defined by the Group variable.

### Usage

```
MatchW(Y = NULL, Tr, X, Group = NULL, estimand = "ATT", M = 1, exact = NULL, caliper = 0.25, weights = NULL, replace = TRUE, ties = TRUE, ...)
```

# **Arguments**

Y A	vector containing th	ne outcome of interest.
-----	----------------------	-------------------------

Tr A vector indicating the treated and control units.

X A matrix of covariates we wish to match on. This matrix should contain all

confounders or the propensity score or a combination of both.

Group A vector describing the clustering structure (typically the cluster ID). This can be any numeric vector of the same length of Tr and X containing integer numbers in ascending order otherwise an error message will be returned. Default is NULL,

however if Group is missing, NULL or it contains only one value the output of

the Match function is returned with a warning.

The causal estimand desired, one of "ATE", "ATT" and "ATC", which stand for estimand Average Treatment Effect, Average Treatment effect on the Treated and on the Controls, respectively. Default is "ATT". The number of matches which are sought for each unit. Default is 1 ("one-to-one М matching"). exact An indicator for whether exact matching on the variables contained in X is desired. Default is FALSE. This option has precedence over the caliper option. A maximum allowed distance for matching units. Units for which no match caliper was found within caliper distance are discarded. Default is 0.25. The caliper is interpreted in standard deviation units of the unclustered data for each variable. For example, if caliper=0.25 all matches at distance bigger than 0.25 times the standard deviation for any of the variables in X are discarded. weights A vector of specific observation weights. replace Matching can be with or without replacement depending on whether matches can be re-used or not. Default is TRUE. ties An indicator for dealing with multiple matches. If more than M matches are found for each unit the additional matches are a) wholly retained with equal weights if ties=TRUE; b) a random one is chosen if ties=FALSE. Default is TRUE.

### **Details**

This function is meant to be a natural extension of the Match function to clustered data. It retains the main arguments of Match but it has additional output showing matching results cluster by cluster. It differs from wrapper Matchby in package Matching in the way standard errors are calculated and because the caliper is in standard deviation units of the covariates on the overall dataset (so the caliper is the same for all clusters). Moreover, observation weights are available.

Note that additional arguments of the Match function are not used.

### Value

The index of control observations in the matched dataset. index.control The index of control observations in the matched dataset. index.treated index.dropped The index of dropped observations due to the exact or caliper option. Note that these observations are treated if estimand is "ATT", controls if "ATC". est The causal estimate. This is provided only if Y is not null. If estimand is "ATT" it is the (weighted) mean of Y in matched treated units minus the (weighted) mean of Y in matched controls. Equivalently, it is the weighted average of the within-cluster ATTs, with weights given by cluster sizes in the matched dataset. A model-based standard error for the causal estimand. This is a cluster robust se estimator of the standard error for the linear model: Y ~ constant+Tr, run on the matched dataset (see cluster.vcov for details on how this estimator is obtained). Note that these standard errors differ from a weighted average of cluster specific standard errors provided by the Matchby function, which are generally larger. Estimating standard errors for causal parameters with clustered data is an active field of research and there is no perfect solution to date.

mdata A list containing the matched datasets produced by MatchPW. Three datasets are

included in this list: Y, Tr and X. The matched dataset for Group can be recovered

by rbind(Group[index.treated],Group[index.control]).

orig.treated.nobs.by.group

The original number of treated observations by group in the dataset.

orig.control.nobs.by.group

The original number of control observations by group in the dataset.

orig.dropped.nobs.by.group

The number of dropped observations by group after within cluster matching.

orig. nobs The original number of observations in the dataset.

orig.wnobs The original number of weighted observations in the dataset.

orig.treated.nobs

The original number of treated observations in the dataset.

orig.control.nobs

The original number of control observations in the dataset.

wnobs the number of weighted observations in the matched dataset.

caliper The caliper used.

intcaliper The internal caliper used.

exact The value of the exact argument.

ndrops.matches The number of matches dropped either because of the caliper or exact option (or

because of forcing the match within-clusters).

estimand The estimand required.

### Note

The function returns an object of class CMatch. The CMatchBalance function can be used to examine the covariate balance before and after matching (see the examples below).

schools

Schools data set (NELS-88)

# Description

Data set used by Kreft and De Leeuw in their book *Introducing Multilevel Modeling, Sage (1988)* to analyse the relationship between math score and time spent by students to do math homework. The data set is a subsample of NELS-88 data consisting of 10 handpicked schools from the 1003 schools in the full data set. Students are nested within schools and information is available both at the school and student level.

# Usage

```
data("schools")
```

20 schools

### **Format**

```
A data frame with 260 observations on the following 19 variables.
schid School ID: a numeric vector identyfing each school.
stuid The student ID.
ses Socioeconomic status.
meanses Mean ses for the school.
homework The number of hours spent weekly doing homeworks.
white A dummy for white race (=1) versus non-white (=0).
parented Parents highest education level.
public Public school: 1=public, 0=non public.
ratio Student-teacher ratio.
percmin Percent minority in school.
math Math score
sex Sex: 1=male, 2=female.
race Race of student, 1=asian, 2=Hispanic, 3=Black, 4=White, 5=Native American.
sctype Type of school: 1=public, 2=catholic, 3= Private other religion, 4=Private non-r.
cstr Classroom environment structure: ordinal from 1=not accurate to 5=very much accurate.
scsize School size: ordinal from 1=[1,199) to 7=[1200+).
urban Urbanicity: 1=Urban, 2=Suburban, 3=Rural.
region Geographic region of the school: NE=1,NC=2,South=3,West=4.
schnum Standardized school ID.
```

summary.CMatch

Summarizing output from MatchW and MatchPW

# **Description**

summary method for MatchW and MatchPW

### Usage

```
## S3 method for class 'CMatch'
summary(object, ..., full = FALSE, digits = 5)
```

# **Arguments**

object An object of class "CMatch".

... Other options for the generic summary function.

full A flag for whether the unadjusted estimates and naive standard errors should

also be summarized.

digits The number of significant digits that should be displayed.

### **Details**

A summary of most important output from a "CMatch" object, including size of matched dataset and estimates (if Y is not NULL). If *Group* contains only one value the output is the same of the summary method of package Matching. Otherwise the output shows also the distribution of treated (control) observations *by group* and the distribution of dropped (because of 'caliper' or 'exact' option), also by group.

# Note

Naive standard errors are not available when there is more than one group so the full parameter is ineffective in that case.

summary.CMatch 23
