Package 'MuMIn'

April 15, 2020

Type Package

Title Multi-Model Inference

Version 1.43.17

Date 2020-04-14

Encoding UTF-8

Author Kamil Bartoń

Maintainer Kamil Bartoń < kamil.barton@go2.pl>

Description Tools for performing model selection and model averaging. Automated model selection through subsetting the maximum model, with optional constraints for model inclusion. Model parameter and prediction averaging based on model weights derived from information criteria (AICc and alike) or custom model weighting schemes.

MuMIn-package 3

MuMIn-package Multi-model inference

Description

The package **MuMIn** contains functions to streamline the information-theoretic model selection and carry out model averaging based on information criteria.

Details

The collection of functions includes:

dredge performs an automated model selection with subsets of the supplied 'global' model, and optional choices of other model properties (such as different link functions). The set of models may be generated either with 'all possible' combinations or tailored according to the conditions specified.

pdredge does the same, but can parallelize model fitting process using a cluster.

model.sel creates a model selection table from hand-picked models.

model.avg calculates model-averaged parameters, with standard errors and confidence intervals. Furthermore, the predict method produces model-averaged predictions.

AICc calculates second-order Akaike information criterion. Some other criteria are provided, see below.

stdize, stdizeFit, std.coef, partial.sd can be used for standardization of data and model coefficients by Standard Deviation or Partial Standard Deviation.

For a complete list of functions, use library(help = "MuMIn").

By default, AIC_c is used to rank the models and to obtain model weights, though any other information criteria can be utilised. At least the following ones are currently implemented in R: AIC and BIC in package **stats**, and QAIC, QAICC, ICOMP, CAICF, and Mallows' Cp in **MuMIn**. There is also DIC extractor for MCMC models, and QIC for GEE.

Most of R's common modelling functions are supported, for a full inventory see the list of supported models.

Apart from the "regular" information criteria, model averaging can be performed using various types of model weighting algorithms: Bates-Granger, bootstrapped, cos-squared, jackknife, stacking, or ARM. These weighting functions apply mostly to glms.

4 AICc

See Also

AIC, step or stepAIC for stepwise model selection by AIC.

Examples

AICc

Second-order Akaike Information Criterion

Description

Calculate Second-order Akaike Information Criterion for one or several fitted model objects (AIC $_c$, AIC for small samples).

Usage

```
AICc(object, ..., k = 2, REML = NULL)
```

Arguments

object	a fitted model object for which there exists a logLik method, or a "logLik" object.
	optionally more fitted model objects.
k	the 'penalty' per parameter to be used; the default $k = 2$ is the classical AIC.
REML	optional logical value, passed to the logLik method indicating whether the restricted log-likelihood or log-likelihood should be used. The default is to use the method used for model estimation.

AICc 5

Value

If just one object is provided, returns a numeric value with the corresponding AIC_c ; if more than one object are provided, returns a data. frame with rows corresponding to the objects and columns representing the number of parameters in the model (df) and AIC_c .

Note

 AIC_c should be used instead AIC when sample size is small in comparison to the number of estimated parameters (Burnham & Anderson 2002 recommend its use when n/K < 40).

6 arm.glm

```
## Not run:
# the same result:
model.avg(fmList, rank = "AICc", rank.args = list(REML = FALSE))
## End(Not run)
```

arm.glm

Adaptive Regression by Mixing

Description

Combine all-subsets GLMs using the ARM algorithm. Calculate ARM weights for a set of models.

Usage

```
arm.glm(object, R = 250, weight.by = c("aic", "loglik"), trace = FALSE) armWeights(object, ..., data, weight.by = c("aic", "loglik"), R = 1000)
```

Arguments

object	for arm.glm, a fitted "global" glm object. For armWeights, a fitted glm object, or a list of such, or an "averaging" object.
	more fitted model objects.
R	number of permutations.
weight.by	indicates whether model weights should be calculated with AIC or log-likelihood.
trace	if TRUE, information is printed during the running of arm.glm.
data	a data frame in which to look for variables for use with prediction. If omitted, the fitted linear predictors are used.

Details

For each of all-subsets of the "global" model, parameters are estimated using randomly sampled half of the data. Log-likelihood given the remaining half of the data is used to calculate AIC weights. This is repeated R times and mean of the weights is used to average all-subsets parameters estimated using complete data.

Value

arm.glm returns an object of class "averaging" containing only "full" averaged coefficients. See model.avg for object description.

armWeights returns a numeric vector of model weights.

arm.glm 7

Note

Number of parameters is limited to floor(nobs(object) / 2) -1. All-subsets respect marginality constraints.

8 Beetle

Beetle

Flour beetle mortality data

Description

Mortality of flour beetles ($Tribolium\ confusum$) due to exposure to gaseous carbon disulfide CS_2 , from Bliss (1935).

Usage

Beetle

Format

Beetle is a data frame with 5 elements.

Prop a matrix with two columns named **nkilled** and **nsurvived mortality** observed mortality rate **dose** the dose of CS_2 in mg/L **n.tested** number of beetles tested **n.killed** number of beetles killed.

```

BGWeights

Bates-Granger model weights

Description

Computes empirical weights based on out of sample forecast variances, following Bates and Granger (1969).

Usage

```
BGWeights(object, ..., data, force.update = FALSE)
```

Arguments

object, ... two or more fitted glm objects, or a list of such, or an "averaging" object.

data a data frame containing the variables in the model.

force.update if TRUE, the much less efficient method of updating glm function will be used rather than directly via glm.fit. This only applies to glms, in case of other model types update is always used.

Details

Bates-Granger model weights are calculated using prediction covariance. To get the estimate of prediction covariance, the models are fitted to randomly selected half of data and prediction is done on the remaining half. These predictions are then used to compute the variance-covariance between models, Σ . Model weights are then calculated as $w_{BG} = (1'\Sigma^{-1}1)^{-1}1\Sigma^{-1}$, where 1 a vector of 1-s.

Bates-Granger model weights may be outside of the [0,1] range, which may cause the averaged variances to be negative. Apparently this method works best when data is large.

Value

The function returns a numeric vector of model weights.

bootWeights 11

Note

For matrix inversion, ginv from package MASS is more stable near singularities than solve. It will be used as a fallback if solve fails and MASS is available.

```
Weights, model.avg
```

Other model.weights: bootWeights, cos2Weights, jackknifeWeights, stackingWeights

Examples

```
fm <- glm(Prop ~ mortality + dose, family = binomial, Beetle, na.action = na.fail)
models <- lapply(dredge(fm, evaluate = FALSE), eval)
ma <- model.avg(models)

# this produces warnings because of negative variances:
set.seed(78)
Weights(ma) <- BGWeights(ma, data = Beetle)
coefTable(ma, full = TRUE)

# SE for prediction is not reliable if some or none of coefficient's SE
# are available
predict(ma, data = test.data, se.fit = TRUE)
coefTable(ma, full = TRUE)</pre>
```

bootWeights

Bootstrap model weights

Description

Computes model weights using bootstrap.

Usage

```
bootWeights(object, ..., R, rank = c("AICc", "AIC", "BIC"))
```

12 Cement

Arguments

```
object, ... two or more fitted glm objects, or a list of such, or an "averaging" object.

R the number of replicates.

rank a character string, specifying the information criterion to use for model ranking.

Defaults to AICc.
```

Details

The models are fitted repeatedly to a resampled data set and ranked using AIC-type criterion. The model weights represent the proportion of replicates when a model has the lowest IC value.

Value

The function returns a numeric vector of model weights.

cos2Weights

Cos-squared model weights

Description

Calculates cos-squared model weights, following the algorithm outlined in the appendix of Garthwaite & Mubwandarikwa (2010).

Usage

```
cos2Weights(object, ..., data, eps = 1e-06, maxit = 100,
predict.args = list())
```

Arguments

object, ... two or more fitted glm objects, or a list of such, or an "averaging" object.

Currently only lm and glm objects are accepted.

data a test data frame in which to look for variables for use with prediction. If omitted, the fitted linear predictors are used.

eps tolerance for determining convergence.

maxit maximum number of iterations.

predict.args optionally, a list of additional arguments to be passed to predict.

Value

The function returns a numeric vector of model weights.

```

dredge

Automated model selection

Description

Generate a model selection table of models with combinations (subsets) of fixed effect terms in the global model, with optional rules for model inclusion.

Usage

```
dredge(global.model, beta = c("none", "sd", "partial.sd"), evaluate = TRUE,
    rank = "AICc", fixed = NULL, m.lim = NULL, m.min, m.max, subset,
    trace = FALSE, varying, extra, ct.args = NULL, ...)

## S3 method for class 'model.selection'
print(x, abbrev.names = TRUE, warnings = getOption("warn") != -1L, ...)
```

Arguments

global.model a fitted 'global' model object. See 'Details' for a list of supported types.

beta indicates whether and how the coefficients are standardized, and must be one of

"none", "sd" or "partial.sd". You can specify just the initial letter. "none" corresponds to unstandardized coefficients, "sd" and "partial.sd" to coefficients standardized by SD and Partial SD, respectively. For backwards compatibility, logical value is also accepted, TRUE is equivalent to "sd" and FALSE to

"none". See std. coef.

evaluate whether to evaluate and rank the models. If FALSE, a list of unevaluated calls

is returned.

rank optional custom rank function (returning an information criterion) to be used

instead AICc, e.g. AIC, QAIC or BIC. See 'Details'.

fixed optional, either a single-sided formula or a character vector giving names of

terms to be included in all models. See 'Subsetting'.

m.lim, m.max, m.min

optionally, the limits c(lower, upper) for the number of terms in a single model (excluding the intercept). An NA means no limit. See 'Subsetting'. Specifying

limits as m.min and m.max is allowed for backward compatibility.

subset logical expression describing models to keep in the resulting set. See 'Subset-

ting'.

trace if TRUE or 1, all calls to the fitting function are printed before actual fitting takes

place. If trace > 1, a progress bar is displayed.

varying optionally, a named list describing the additional arguments to vary between the

generated models. Item names correspond to the arguments, and each item provides a list of choices (i.e. list(arg1 = list(choice1, choice2,...),...)). Complex elements in the choice list (such as family objects) should be either named (uniquely) or quoted (unevaluated, e.g. using alist, see quote), other-

wise the result may be visually unpleasant. See example in Beetle.

extra optional additional statistics to include in the result, provided as functions, func-

tion names or a list of such (best if named or quoted). Similarly as in rank argument, each function must accept fitted model object as an argument and return (a value coercible to) a numeric vector. These can be e.g. additional information criteria or goodness-of-fit statistics. The character strings "R^2" and "adjR^2" are treated in a special way, and will add a likelihood-ratio based R^2 and modified- R^2 respectively to the result (this is more efficient than using

r.squaredLR directly).

x a model.selection object, returned by dredge.

abbrev.names should printed term names be abbreviated? (useful with complex models).

warnings if TRUE, errors and warnings issued during the model fitting are printed below

the table (only with pdredge). To permanently remove the warnings, set the

object's attribute "warnings" to NULL.

ct.args optional list of arguments to be passed to coefTable (e.g. dispersion param-

eter for glm affecting standard errors used in subsequent model averaging).

optional arguments for the rank function. Any can be an unevaluated expression, in which case any x within it will be substituted with the current model.

Details

Models are fitted through repeated evaluation of modified call extracted from the global.model (in a similar fashion as with update). This approach, while robust in that it can be applied to most model types through the usual formula interface, may have considerable computational overhead.

Note that the number of combinations grows exponentially with the number of predictors $(2^N, less)$ when interactions are present, see below).

The fitted model objects are not stored in the result. To get (possibly a subset of) the models, use get.models on the object returned by dredge. Another way of getting all the models is to run lapply(dredge(...,evaluate = FALSE),eval), which avoids fitting the models twice.

For a list of model types that can be used as a global.model see the list of supported models. Modelling functions not storing call in their result should be evaluated *via* the wrapper function created by updateable.

Information criterion: rank is found by a call to match. fun and may be specified as a function or a symbol or a character string specifying a function to be searched for from the environment of the call to dredge. The function rank must accept a model object as its first argument and always return a scalar.

Interactions: By default, marginality constraints are respected, so "all possible combinations" include only those containing interactions with their respective main effects and all lower-order terms. However, if global.model makes an exception to this principle (e.g. due to a nested design such as a / (b + d)), this will be reflected in the subset models.

Subsetting: There are three ways to constrain the resulting set of models: setting limits to the number of terms in a model with m.lim, binding the term(s) to all models with fixed, and more complex rules can be applied using argument subset. To be included in the selection table, the model formulation must satisfy all these conditions.

subset can take either a form of an *expression* or a *matrix*. The latter should be a lower triangular matrix with logical values, where columns and rows correspond to global.model terms. Value subset["a","b"] == FALSE will exclude any model containing both terms a and b. demo(dredge.subset) has examples of using the subset matrix in conjunction with correlation matrices to exclude models containing collinear predictors.

Term names appearing in fixed and subset must be given in the exact form as returned by getAllTerms(global.model), which can differ from the original term names (e.g. the interaction term components are ordered alphabetically).

In the form of expression, the argument subset acts in a similar fashion to that in the function subset for data.frames: model terms can be referred to by name as variables in the expression, with the difference being that are interpreted as logical values (i.e. equal to TRUE if the term exists in the model).

The expression can contain any of the global.model term names, as well as names of the varying list items. global.model term names take precedence when identical to names of varying, so to avoid ambiguity varying variables in subset expression should be enclosed in V() (e.g. V(family) == "Gamma" assuming that varying is something like list(family = c("Gamma",...))).

If item names in varying are missing, the items themselves are coerced to names. Call and symbol elements are represented as character values (*via* deparse), and everything except numeric, logical, character and NULL values is replaced by item numbers (e.g. varying = list(family =

list(..., Gamma) should be referred to as subset = V(family) == 2. This can quickly become confusing, therefore it is recommended to use named lists. demo(dredge.varying) provides examples.

The with(x) and with(+x) notation indicates, respectively, any and all interactions including the main effect term x. This is only effective with marginality exceptions. The extended form with(x,order) allows for specifying the order of interaction of terms which x is part of. For instance, with(b,2:3) selects models with at least one second- or third-order interaction of the variable b. The second (positional) argument is coerced to an integer vector. The "dot" notation .(x) is an alias for with.

The special variable `*nvar*` (backtick-quoted), in the subset expression is equal to the number of terms in the model (**not** the number of estimated parameters).

To make the inclusion of a model term conditional on the presence of another one, the function dc ("dependency chain") can be used in the subset expression. dc takes any number of term names as arguments, and allows a term to be included only if all preceding ones are also present (e.g. subset = dc(a,b,c) allows for models a, a+b and a+b+c but not b, c, b+c or a+c).

subset expression can have a form of an unevaluated call, expression object, or a one-sided formula. See 'Examples'.

Compound model terms (such as interactions, 'as-is' expressions within I() or smooths in gam) should be enclosed within curly brackets (e.g. $\{s(x,k=2)\}$), or backticks (like non-syntactic names, e.g. `s(x,k=2)`), unless they are arguments to . or dc. Backticks-quoted names must match exactly (including whitespace) the term names as returned by getAllTerms.

subset expression syntax summary:

a & b indicates that model terms a and b must be present (see Logical Operators)

 $\{\log(x,2)\}\$ or $(\log(x,2))$ represent a complex model term $\log(x,2)$

V(x) represents a varying item x

with (x) indicates that at least one term containing the main effect term x must be present

with (+x) indicates that all the terms containing the main effect term x must be present

with (x, n:m) indicates that at least one term containing an n-th to m-th order interaction term of x must be present

dc(a, b, c,...) 'dependency chain': b is allowed only if a is present, and c only if both a and b are present, etc.

'*nvar*' the number of terms in the model.

To simply keep certain terms in all models, use of argument fixed is much more efficient. The fixed formula is interpreted in the same manner as model formula and so the terms must not be quoted.

Missing values: Use of na.action = "na.omit" (R's default) or "na.exclude" in global.model must be avoided, as it results with sub-models fitted to different data sets if there are missing values. An error is thrown if it is detected.

It is a common mistake to give na.action as an argument in the call to dredge (typically resulting in an error from the rank function to which the argument is passed through '...'), while the correct way is either to pass na.action in the call to the global model or to set it as a global option.

Intercept:

If present in the global.model, the intercept will be included in all sub-models.

Methods: There are subset and plot methods, the latter creates a graphical representation of model weights and per-model term sum of weights. Coefficients can be extracted with coef or coefTable.

Value

An object of class c("model.selection", "data.frame"), being a data.frame, where each row represents one model. See model.selection.object for its structure.

Note

Users should keep in mind the hazards that a "thoughtless approach" of evaluating all possible models poses. Although this procedure is in certain cases useful and justified, it may result in selecting a spurious "best" model, due to the model selection bias.

"Let the computer find out" is a poor strategy and usually reflects the fact that the researcher did not bother to think clearly about the problem of interest and its scientific setting (Burnham and Anderson, 2002).

pdredge is a parallelized version of this function (uses a cluster).

get.models, model.avg. model.sel for manual model selection tables.

Possible alternatives: glmulti in package glmulti and bestglm (bestglm). regsubsets in package leaps also performs all-subsets regression.

Lasso variable selection provided by various packages, e.g. glmnet, lars or glmmLasso.

```
# Example from Burnham and Anderson (2002), page 100:
# prevent fitting sub-models to different datasets

options(na.action = "na.fail")

fm1 <- lm(y ~ ., data = Cement)
dd <- dredge(fm1)
subset(dd, delta < 4)

# Visualize the model selection table:

par(mar = c(3,5,6,4))
plot(dd, labAsExpr = TRUE)

# Model average models with delta AICc < 4
model.avg(dd, subset = delta < 4)</pre>
```

exprApply 19

```
#or as a 95% confidence set:
model.avg(dd, subset = cumsum(weight) <= .95) # get averaged coefficients</pre>
#'Best' model
summary(get.models(dd, 1)[[1]])
## Not run:
# Examples of using 'subset':
# keep only models containing X3
dredge(fm1, subset = ~ X3) # subset as a formula
dredge(fm1, subset = expression(X3)) # subset as expression object
# the same, but more effective:
dredge(fm1, fixed = "X3")
# exclude models containing both X1 and X2 at the same time
dredge(fm1, subset = !(X1 && X2))
# Fit only models containing either X3 or X4 (but not both);
\# include X3 only if X2 is present, and X2 only if X1 is present.
dredge(fm1, subset = dc(X1, X2, X3) \&\& xor(X3, X4))
# the same as above, without "dc"
dredge(fm1, subset = (X1 | !X2) && (X2 | !X3) && xor(X3, X4))
# Include only models with up to 2 terms (and intercept)
dredge(fm1, m.lim = c(0, 2))
## End(Not run)
# Add R^2 and F-statistics, use the 'extra' argument
dredge(fm1, m.lim = c(NA, 1), extra = c("R^2", F = function(x))
    summary(x)$fstatistic[[1]]))
# with summary statistics:
dredge(fm1, m.lim = c(NA, 1), extra = list(
    "R^2", "*" = function(x) {
        s <- summary(x)</pre>
        c(Rsq = s$r.squared, adjRsq = s$adj.r.squared,
            F = s$fstatistic[[1]])
    })
)
# Add other information criteria (but rank with AICc):
dredge(fm1, m.lim = c(NA, 1), extra = alist(AIC, BIC, ICOMP, Cp))
```

exprApply

Apply a function to calls inside an expression

Description

Apply function FUN to each occurrence of a call to what() (or a symbol what) in an unevaluated expression. It can be used for advanced manipulation of expressions. Intended primarily for internal

20 exprApply

use.

Usage

```
exprApply(expr, what, FUN, ..., symbols = FALSE)
```

Arguments

expr an unevaluated expression.

what character string giving the name of a function. Each call to what inside expr will

be passed to FUN. what can be also a character representation of an operator or parenthesis (including curly and square brackets) as these are primitive functions

in R. Set what to NA to match all names.

FUN a function to be applied.

symbols logical value controlling whether FUN should be applied to symbols as well as

calls.

... optional arguments to FUN.

Details

FUN is found by a call to match. fun and can be either a function or a symbol (e.g., a backquoted name) or a character string specifying a function to be searched for from the environment of the call to exprApply.

Value

A (modified) expression.

Note

If expr has a source reference information ("srcref" attribute), modifications done by exprApply will not be visible when printed unless srcref is removed. However, exprApply does remove source reference from any function expression inside expr.

Author(s)

Kamil Bartoń

See Also

Expression-related functions: substitute, expression, quote and bquote.

Similar function walkCode exists in package codetools.

Functions useful inside FUN: as.name, as.call, call, match.call etc.

exprApply 21

```
### simple usage:
# print all Y(...) terms in a formula (note that symbol "Y" is omitted):
exprApply(~X(1) + Y(2 + Y(4)) + N(Y + Y(3)), "Y", print)
# replace X() with log(X, base = n)
exprApply(expression(A() + B() + C()), c("A", "B", "C"), function(expr, base) {
    expr[[2]] <- expr[[1]]
    expr[[1]] <- as.name("log")</pre>
    expr$base <- base
    expr
}, base = 10)
###
# TASK: fit lm with two poly terms, varying the degree from 1 to 3 in each.
\# lm(y \sim poly(X1, degree = a) + poly(X2, degree = b), data = Cement)
# for a = \{1,2,3\} and b = \{1,2,3\}
# First we create a wrapper function for lm. Within it, use "exprApply" to add
# "degree" argument to all occurences of "poly()" having "X1" or "X2" as the
# first argument. Values for "degree" are taken from arguments "d1" and "d2"
lmpolywrap <- function(formula, d1 = NA, d2 = NA, ...) {</pre>
    cl <- origCall <- match.call()</pre>
    cl[[1]] <- as.name("lm")</pre>
    cl$formula <- exprApply(formula, "poly", function(e, degree, x) {</pre>
        i \leftarrow which(e[[2]] == x)[1]
        if(!is.na(i) && !is.na(degree[i])) e$degree <- degree[i]</pre>
    , degree = c(d1, d2), x = c("X1", "X2"))
    cl$d1 <- cl$d2 <- NULL
    fit <- eval(cl, parent.frame())</pre>
    fit$call <- origCall # replace the stored call
    fit
}
# global model:
fm \leftarrow lmpolywrap(y \sim poly(X1) + poly(X2), data = Cement)
# Use "dredge" with argument "varying" to generate calls of all combinations of
# degrees for poly(X1) and poly(X2). Use "fixed = TRUE" to keep all global model
# terms in all models.
# Since "dredge" expects that global model has all the coefficients the
# submodels can have, which is not the case here, we first generate model calls,
# evaluate them and feed to "model.sel"
modCalls <- dredge(fm,</pre>
    varying = list(d1 = 1:3, d2 = 1:3),
    fixed = TRUE,
    evaluate = FALSE
)
```

22 Formula manipulation

```
model.sel(models <- lapply(modCalls, eval))

# Note: to fit *all* submodels replace "fixed = TRUE" with:
# "subset = (d1==1 || {poly(X1)}) && (d2==1 || {poly(X2)})"

# This is to avoid fitting 3 identical models when the matching "poly()" term is
# absent.</pre>
```

Formula manipulation Manipulate model formulas

Description

simplify. formula rewrites a formula using shorthand notation. Currently only the factor crossing operator * is applied, so that expanded expression such as a+b+a:b becomes a*b. expand. formula does the opposite, additionally expanding other expressions, i.e. all nesting (/), grouping and ^.

Usage

```
simplify.formula(x)
expand.formula(x)
```

Arguments

x a formula or an object from which it can be extracted (such as a fitted model object).

Author(s)

Kamil Bartoń

```
formula
```

```
delete.response, drop.terms, and reformulate
```

```
simplify.formula(y \sim a + b + a:b + (c + b)^2)
simplify.formula(y \sim a + b + a:b + 0)
expand.formula(\sim a \times b)
```

get.models 23

get.models	Retrieve models from selection table	

Description

Generate or extract a list of fitted model objects from a "model.selection" table, optionally using parallel computation in a cluster.

Usage

```
get.models(object, subset, cluster = NA, ...)
```

Arguments

object	object returned by dredge.
subset	subset of models, an expression evaluated within the model selection table (see 'Details').
cluster	optionally, a "cluster" object. If it is a valid cluster, models are evaluated using parallel computation.
•••	additional arguments to update the models. For example, in 1me one may want to use method = "REML" while using "ML" for model selection.

Details

The argument subset must be explicitly provided. This is to assure that a potentially long list of models is not fitted unintentionally. To evaluate all models, set subset to NA or TRUE.

If subset is a character vector, it is interpreted as names of rows to be selected.

Value

list of fitted model objects.

Note

Alternatively, getCall and eval can be used to compute a model out of the "model.selection" table (e.g. eval(getCall(<model.selection>,i)), where i is the model index or name).

Using get.models following dredge is not efficient as the requested models have to be fitted again. If the number of generated models is reasonable, consider using

lapply(dredge(...,evaluate = FALSE), eval), which generates a list of all model calls and evaluates them into a list of model objects. This avoids fitting the models twice.

pget.models is still available, but is deprecated.

References

Burnham, K. P. and Anderson, D. R (2002) *Model selection and multimodel inference: a practical information-theoretic approach*. 2nd ed. New York, Springer-Verlag.

Information criteria Various information criteria

Description

Calculate Mallows' Cp and Bozdogan's ICOMP and CAIFC information criteria.

Extract or calculate Deviance Information Criterion from MCMCglmm and merMod object.

Usage

```
Cp(object, ..., dispersion = NULL)
ICOMP(object, ..., REML = NULL)
CAICF(object, ..., REML = NULL)
DIC(object, ...)
```

Arguments

object a fitted model object (in case of ICOMP and CAICF, logLik and vcov methods

must exist for the object). For DIC, an object of class "MCMCglmm" or "merMod".

... optionally more fitted model objects.

dispersion the dispersion parameter. If NULL, it is inferred from object.

REML optional logical value, passed to the logLik method indicating whether the re-

stricted log-likelihood or log-likelihood should be used. The default is to use the

method used for model estimation.

Details

Mallows' Cp statistic is the residual deviance plus twice the estimate of σ^2 times the residual degrees of freedom. It is closely related to AIC (and a multiple of it if the dispersion is known).

ICOMP (I for informational and COMP for complexity) penalizes the covariance complexity of the model, rather than the number of parameters directly.

CAICF (C is for 'consistent' and F denotes the use of the Fisher information matrix) includes with penalty the natural logarithm of the determinant of the estimated Fisher information matrix.

26 jackknifeWeights

Value

If just one object is provided, the functions return a numeric value with the corresponding IC; otherwise a data. frame with rows corresponding to the objects is returned.

jackknifeWeights

Jackknifed model weights

Description

Computes model weights optimized for jackknifed model fits.

Usage

```
jackknifeWeights(object, ..., data, type = c("loglik", "rmse"),
  family = NULL, weights = NULL, optim.method = "BFGS", maxit = 1000,
  optim.args = list(), start = NULL, force.update = FALSE,
  py.matrix = FALSE)
```

Arguments

object,	two or more fitted glm objects, or a list of such, or an "averaging" object.
data	a data frame containing the variables in the model. It is optional if all models are glm.
type	a character string specifying the function to minimize. Either "rmse" or "loglik".
family	used only if type = "loglik", a family object to be used for likelihood calculation. Not needed if all models share the same family and link function.
weights	an optional vector of 'prior weights' to be used in the model fitting process. Should be NULL or a numeric vector.

jackknifeWeights 27

optim.method optional, optimisation method, passed to optim.

maxit optional, the maximum number of iterations, passed to optim.

optim.args optional list of other arguments passed to optim.

start starting values for model weights. Numeric of length equal the number of mod-

els.

force.update for glm, the glm.fit function is used for fitting models to the train data, which

is much more efficient. Set to TRUE to use update instead.

py.matrix either a boolean value, then if TRUE a jackknifed prediction matrix is returned

and if FALSE a vector of jackknifed model weights, or a $N \times M$ matrix (number of cases \times number of models) that is interpreted as a jackknifed prediction matrix

and it is used for optimisation (i.e. the jackknife procedure is skipped).

Details

Model weights are chosen (using optim) to minimise RMSE or log-likelihood of the prediction for data point i, of a model fitted omitting that data point i. The jackknife procedure is therefore run for all provided models and for all data points.

Value

The function returns a numeric vector of model weights.

Note

This procedure can give variable results depending on the optimisation method and starting values. It is therefore advisable to make several replicates using different optim.methods. See optim for possible values for this argument.

28 loo

Examples

```
fm <- glm(Prop ~ mortality * dose, binomial(), Beetle, na.action = na.fail)
fits <- lapply(dredge(fm, eval = FALSE), eval)
amJk <- amAICc <- model.avg(fits)
set.seed(666)
Weights(amJk) <- jackknifeWeights(fits, data = Beetle)
coef(amJk)
coef(amAICc)</pre>
```

100

Leave-one-out cross-validation

Description

Computes the RMSE/log-likelihood based on leave-one-out cross-validation.

Usage

```
loo(object, type = c("loglik", "rmse"), ...)
```

Arguments

object a fitted object model, currently only lm/glm is accepted.

type the criterion to use, given as a character string, either "rmse" for Root-Mean-

Square Error or "loglik" for log-likelihood.

... other arguments are currently ignored.

Details

Leave-one-out cross validation is a K-fold cross validation, with K equal to the number of data points in the set N. For all i from 1 to N, the model is fitted to all the data except for i-th row and a prediction is made for that value. The average error is computed and used to evaluate the model.

Value

loo returns a single numeric value of RMSE or mean log-likelihood.

Author(s)

Kamil Bartoń, based on code by Carsten Dormann

References

Dormann, C. et al. (2018) Model averaging in ecology: a review of Bayesian, information-theoretic, and tactical approaches for predictive inference. *Ecological Monographs*, 88, 485–504.

merge.model.selection 29

Examples

```
fm <- lm(y ~ X1 + X2 + X3 + X4, Cement)
loo(fm, type = "1")
loo(fm, type = "r")

## Compare LOO_RMSE and AIC/c
options(na.action = na.fail)
dd <- dredge(fm, rank = loo, extra = list(AIC, AICc), type = "rmse")
plot(loo ~ AIC, dd, ylab = expression(LOO[RMSE]), xlab = "AIC/c")
points(loo ~ AICc, data = dd, pch = 19)
legend("topleft", legend = c("AIC", "AICc"), pch = c(1, 19))</pre>
```

merge.model.selection Combine model selection tables

Description

Combine two or more model selection tables.

Usage

```
## S3 method for class 'model.selection'
merge(x, y, suffixes = c(".x", ".y"), ...)
## S3 method for class 'model.selection'
rbind(..., deparse.level = 1, make.row.names = TRUE)
```

Arguments

```
x, y, ... model.selection objects to be combined. (...ignored in merge)
suffixes a character vector with two elements that are appended respectively to row names of the combined tables.

make.row.names logical indicating if unique and valid row.names should be constructed from the arguments.

deparse.level ignored.
```

Value

A "model.selection" object containing models (rows) from all provided tables.

Note

Both Δ_{IC} values and Akaike weights are recalculated in the resulting tables.

Models in the combined model selection tables must be comparable, i.e. fitted to the same data, however only very basic checking is done to verify that. The models must also be ranked by the same information criterion.

Unlike the merge method for data. frame, this method appends second table to the first (similarly to rbind).

Kamil Bartoń

See Also

```
dredge, model.sel, merge, rbind.
```

Examples

Model utilities

Model utility functions

Description

These functions extract or calculate various values from provided fitted model objects(s). They are mainly meant for internal use.

coeffs extracts model coefficients;

getAllTerms extracts independent variable names from a model object;

coefTable extracts a table of coefficients, standard errors and associated degrees of freedom when possible;

get.response extracts response variable from fitted model object;

model.names generates shorthand (alpha)numeric names for one or several fitted models.

Usage

```
coeffs(model)
getAllTerms(x, ...)
## S3 method for class 'terms'
getAllTerms(x, intercept = FALSE, offset = TRUE, ...)
coefTable(model, ...)
## S3 method for class 'averaging'
coefTable(model, full = FALSE, adjust.se = TRUE, ...)
```

Model utilities 31

```
## S3 method for class 'lme'
coefTable(model, adjustSigma, ...)
## S3 method for class 'gee'
coefTable(model, ..., type = c("naive", "robust"))
get.response(x, data = NULL, ...)
model.names(object, ..., labels = NULL, use.letters = FALSE)
```

Arguments

model a fitted model object.

object a fitted model object or a list of such objects.

x a fitted model object or a formula.

offset should 'offset' terms be included?

intercept should terms names include the intercept?

full, adjust.se

logical, apply to "averaging" objects. If full is TRUE, the full model-averaged coefficients are returned, and subset-averaged ones otherwise. If adjust.se is

TRUE, inflated standard errors are returned. See 'Details' in par.avg.

adjustSigma See summary.lme.

type for GEE models, the type of covariance estimator to calculate returned standard

errors on. Either "naive" or "robust" ('sandwich').

labels optionally, a character vector with names of all the terms, e.g. from a global

model. model.names enumerates the model terms in order of their appearance in the list and in the models. Therefore changing the order of the models leads

to different names. Providing labels prevents that.

... in model.names, more fitted model objects. In coefTable arguments that are

passed to appropriate vcov or summary method (e.g. dispersion parameter for glm may be used here). In get.response, if data is given, arguments to be

passed to model. frame. In other functions may be silently ignored.

data a data.frame, list or environment (or object coercible to a data.frame),

containing the variables in x. Required only if x is a formula, otherwise it can

be used to get the response variable for a different data set.

use.letters logical, whether letters should be used instead of numeric codes.

Details

The functions coeffs, getAllTerms and coefTable provide interface between the model object and model.avg (and dredge). Custom methods can be written to provide support for additional classes of models.

32 model.avg

Note

coeffs's value is in most cases identical to that returned by coef, the only difference being it returns fixed effects' coefficients for mixed models, and the value is always a named numeric vector.

Use of tTable is deprecated in favour of coefTable.

Author(s)

Kamil Bartoń

model.avg

Model averaging

Description

Model averaging based on an information criterion.

Usage

```
model.avg(object, ..., revised.var = TRUE)

## Default S3 method:
model.avg(object, ..., beta = c("none", "sd", "partial.sd"),
    rank = NULL, rank.args = NULL, revised.var = TRUE,
    dispersion = NULL, ct.args = NULL)

## S3 method for class 'model.selection'
model.avg(object, subset, fit = FALSE, ..., revised.var = TRUE)
```

Arguments

object	a fitted model object or a list of such objects, or a "model.selection" object. See 'Details'.
•••	for default method, more fitted model objects. Otherwise, arguments that are passed to the default method.
beta	indicates whether and how the component models' coefficients should be standardized. See the argument's description in dredge.
rank	optionally, a rank function (returning an information criterion) to use instead of AICc, e.g. BIC or QAIC, may be omitted if object is a model list returned by get.models or a "model.selection" object. See 'Details'.
rank.args	optional list of arguments for the rank function. If one is an expression, an x within it is substituted with a current model.

model.avg 33

revised.var logical, indicating whether to use the revised formula for standard errors. See par.avg.

dispersion the dispersion parameter for the family used. See summary.glm. This is used currently only with glm, is silently ignored otherwise.

ct.args optional list of arguments to be passed to coefTable (besides dispersion). subset see subset method for "model.selection" object.

fit if TRUE, the component models are fitted using get.models. See 'Details'.

Details

model.avg may be used either with a list of models or directly with a model.selection object (e.g. returned by dredge). In the latter case, the models from the model selection table are not evaluated unless the argument fit is set to TRUE or some additional arguments are present (such as rank or dispersion). This results in a much faster calculation, but has certain drawbacks, because the fitted component model objects are not stored, and some methods (e.g. predict, fitted, model.matrix or vcov) would not be available with the returned object. Otherwise, get.models is called prior to averaging, and ... are passed to it.

For a list of model types that are accepted see list of supported models.

rank is found by a call to match. fun and typically is specified as a function or a symbol or a character string specifying a function to be searched for from the environment of the call to lapply. rank must be a function able to accept model as a first argument and must always return a numeric scalar.

Several standard methods for fitted model objects exist for class averaging, including summary, predict, coef, confint, formula, and vcov.

coef, vcov, confint and coefTable accept argument full that if set to TRUE, the full model-averaged coefficients are returned, rather than subset-averaged ones (when full = FALSE, being the default).

logLik returns a list of logLik objects for the component models.

Value

An object of class "averaging" is a list with components:

msTable	a data.frame with log-likelihood, IC , Δ_{IC} and 'Akaike weights' for the component models. Its attribute "term.codes" is a named vector with numerical representation of the terms in the row names of msTable.
coefficients	a matrix of model-averaged coefficients. "full" coefficients in the first row, "subset" coefficients in the second row. See 'Note'
coefArray	a 3-dimensional array of component models' coefficients, their standard errors and degrees of freedom.
SW	object of class sw containing per-model term sum of model weights over all of the models in which the term appears.
formula	a formula corresponding to the one that would be used in a single model. The formula contains only the averaged (fixed) coefficients.
call	the matched call.

34 model.avg

The object has the following attributes:

rank the rank function used.

modelList optionally, a list of all component model objects. Only if the object was created

with model objects (and not model selection table).

beta Corresponds to the function argument.

nobs number of observations.

revised.var Corresponds to the function argument.

Note

The 'subset' (or 'conditional') average only averages over the models where the parameter appears. An alternative, the 'full' average assumes that a variable is included in every model, but in some models the corresponding coefficient (and its respective variance) is set to zero. Unlike the 'subset average', it does not have a tendency of biasing the value away from zero. The 'full' average is a type of shrinkage estimator, and for variables with a weak relationship to the response it is smaller than 'subset' estimators.

Averaging models with different contrasts for the same factor would yield nonsense results. Currently, no checking for contrast consistency is done.

print method provides a concise output (similarly as for lm). To print more details use summary function, and confint to get confidence intervals.

model.sel

model selection table

Description

Build a model selection table.

Usage

```
model.sel(object, ...)
## Default S3 method:
model.sel(object, ..., rank = NULL, rank.args = NULL,
    beta = c("none", "sd", "partial.sd"), extra)
## S3 method for class 'model.selection'
model.sel(object, rank = NULL, rank.args = NULL, fit = NA,
    ..., beta = c("none", "sd", "partial.sd"), extra)
```

36 model.sel

Arguments

object	a fitted model object, a list of such objects, or a "model.selection" object. more fitted model objects.
• • •	more much moder objects.
rank	optional, custom rank function (returning an information criterion) to use instead of the default AICc, e.g. QAIC or BIC, may be omitted if object is a model list returned by get.models.
rank.args	optional list of arguments for the rank function. If one is an expression, an x within it is substituted with a current model.
fit	logical, stating whether the model objects should be re-fitted if they are not stored in the "model.selection" object. Set to NA to re-fit the models only if this is needed. See 'Details'.
beta	indicates whether and how the component models' coefficients should be standardized. See the argument's description in dredge.
extra	optional additional statistics to include in the result, provided as functions, function names or a list of such (best if named or quoted). See dredge for details.

Details

model.sel used with "model.selection" object will re-fit model objects, unless they are stored in object (in attribute "modelList"), if argument extra is provided, or the requested beta is different than object's "beta" attribute, or the new rank function cannot be applied directly to logLik objects, or new rank.args are given (unless argument fit = FALSE).

Value

An object of class c("model.selection", "data.frame"), being a data.frame, where each row represents one model and columns contain useful information about each model: the coefficients, df, log-likelihood, the value of the information criterion used, Δ_{IC} and 'Akaike weight'. If any arguments differ between the modelling function calls, the result will include additional columns showing them (except for formulas and some other arguments).

See model.selection.object for its structure.

```

model.selection.object

Description of Model Selection Objects

Description

An object of class "model.selection" holds a table of model coefficients and ranking statistics. It is produced by dredge or model.sel.

Value

The object is a data. frame with additional attributes. Each row represents one model. The models are ordered by the information criterion value specified by rank (lowest on top).

Data frame columns:

model terms For numeric covariates these columns hold coefficent value, for factors their

presence in the model. If the term is not present in a model, value is NA.

'varying' arguments

optional. If any arguments differ between the modelling function calls (except for formulas and some other arguments), these will be held in additional

columns (of class "factor").

"df" Number of model parameters

"logLik" Log-likelihood (or quasi-likelihood for GEE)

rank Information criterion value

"delta" Δ_{IC}

"weight" 'Akaike weights'.

Attributes:

model.calls

A list containing model calls (arranged in the same order as in the table). A model call can be retrieved with getCall(*,i) where i is a vector of model index or name (if given as character string).

38 MuMIn-models

The global.model object global Call to the global.model global.call A character string holding all term names. Attribute "interceptLabel" gives terms the name of the intercept term. The rank function used rank A character string, representing the coefficient standardizing method used. Eibeta ther "none", "sd" or "partial.sd" List of matrices of class "coefTable" containing each model's coefficients with coefTables std. errors and associated dfs nobs Number of observations optional (pdredge only). A list of errors and warnings issued by the modelling warnings

function during the fitting, with a model number appended to each.

Most attributes does not need (and should not) be accessed directly, use of extractor functions is preferred. These functions include getCall for retrieving model calls, coefTable and coef for coefficients, and nobs. logLik extracts list of model log-likelihoods (as "logLik" objects), and Weights extracts 'Akaike weights'.

The object has class c("model.selection", "data.frame").

See Also

```
dredge, model.sel.
```

MuMIn-models List of supported models

Description

List of model classes accepted by model.avg, model.sel, and dredge.

Details

Fitted model objects that can be used with model selection and model averaging functions include those produced by:

```
lm, glm (package stats);
rlm, glm.nb and polr (MASS);
multinom (nnet);
lme, gls (nlme);
lmer, glmer (lme4);
cpglm, cpglmm (cplm);
gam, gamm* (mgcv);
gamm4* (gamm4);
```

MuMIn-models 39

```
• gamlss (gamlss);
• glmmML (glmmML);
• glmmadmb (glmmADMB from R-Forge);
• glmmTMB (glmmTMB);
• MCMCglmm* (MCMCglmm);
• asreml (non-free commercial package asreml; allows only for REML comparisons);
• hurdle, zeroinfl (pscl);
• negbin, betabin (class "glimML"), package aod);
• aodml, aodql (aods3);
• betareg (betareg);
• brglm (brglm);
• *sarlm models, spautolm (spatialreg);
• spml* (if fitted by ML, splm);
• coxph, survreg (survival);
• coxme, lmekin (coxme);
• rq (quantreg);
• clm and clmm (ordinal);
• logistf (logistf);
• crunch*, pgls (caper);
• maxlike (maxlike);
• functions from package unmarked (within the class "unmarkedFit");
```

- mark and related functions (class mark from package **RMark**). Currently dredge can only manipulate formula element of the argument model.parameters, keeping its other elements intact.

Generalized Estimation Equation model implementations: geeglm from package geepack, gee from gee, geem from geeM, wgee from wgeesel, and yags from yags (on R-Forge) can be used with QIC as the selection criterion.

Other classes are also likely to be supported, in particular if they inherit from one of the above classes. In general, the models averaged with model avg may belong to different types (e.g. glm and gam), provided they use the same data and response, and if it is valid to do so. This applies also to constructing model selection tables with model.sel.

Note

* In order to use gamm, gamm4, spml (> 1.0.0), crunch or MCMCglmm with dredge, an updateable wrapper for these functions should be created.

See Also

```
model.avg, model.sel and dredge.
```

40 nested

nested	Identify nested models

Description

Find models that are 'nested' within each model in the model selection table.

Usage

```
nested(x, indices = c("none", "numeric", "rownames"), rank = NULL)
```

Arguments

x a "model.selection" object (result of dredge or model.sel).

indices if omitted or "none" then the function checks if, for each model, there are any

higher ranked models nested within it. If "numeric" or "rownames", indices or

names of all nested models are returned. See "Value".

rank the name of the column with the ranking values (defaults to the one before

"delta"). Only used if indices is "none".

Details

In model comparison, a model is said to be "nested" within another model if it contains a subset of parameters of the latter model, but does not include other parameters (e.g. model 'A+B' is nested within 'A+B+C' but not 'A+C+D').

This function can be useful in a model selection approach suggested by Richards (2008), in which more complex variants of any model with a lower IC value are excluded from the candidate set.

Value

A vector of length equal to the number of models (table rows).

If indices = "none" (the default), it is a vector of logical values where *i*-th element is TRUE if any model(s) higher up in the table are nested within it (i.e. if simpler models have lower IC pointed by rank).

For indices other than "none", the function returns a list of vectors of numeric indices or names of models nested within each *i*-th model.

Note

This function determines nesting based only on fixed model terms, within groups of models sharing the same 'varying' parameters (see dredge and example in Beetle).

```
fm <- lm(y ~ X1 + X2 + X3 + X4, data = Cement, na.action = na.fail)
ms <- dredge(fm)

# filter out overly complex models according to the
# "nesting selection rule":
subset(ms, !nested(.)) # dot represents the ms table object

# print model "4" and all models nested within it
nst <- nested(ms, indices = "row")
ms[c("4", nst[["4"]])]

ms$nested <- sapply(nst, paste, collapse = ",")</pre>
```

par.avg

Parameter averaging

Description

Average a coefficient with standard errors based on provided weights. This function is intended chiefly for internal use.

Usage

```
par.avg(x, se, weight, df = NULL, level = 1 - alpha, alpha = 0.05,
    revised.var = TRUE, adjusted = TRUE)
```

42 par.avg

Arguments

x vector of parameters.
se vector of standard errors.

weight vector of weights.

df optional vector of degrees of freedom.

alpha, level significance level for calculating confidence intervals.

revised.var logical, should the revised formula for standard errors be used? See 'Details'.

adjusted logical, should the inflated standard errors be calculated? See 'Details'.

Details

Unconditional standard errors are square root of the variance estimator, calculated either according to the original equation in Burnham and Anderson (2002, equation 4.7), or a newer, revised formula from Burnham and Anderson (2004, equation 4) (if revised.var = TRUE, this is the default). If adjusted = TRUE (the default) and degrees of freedom are given, the adjusted standard error estimator and confidence intervals with improved coverage are returned (see Burnham and Anderson 2002, section 4.3.3).

Value

par. avg returns a vector with named elements:

Coefficient model coefficients

SE unconditional standard error

Adjusted SE adjusted standard error

Lower CI, Upper CI

unconditional confidence intervals.

model.avg for model averaging.

pdredge 43

pdredge

Automated model selection using parallel computation

Description

Parallelized version of dredge.

Usage

```
pdredge(global.model, cluster = NA,
   beta = c("none", "sd", "partial.sd"), evaluate = TRUE, rank = "AICc",
   fixed = NULL, m.lim = NULL, m.min, m.max, subset, trace = FALSE,
   varying, extra, ct.args = NULL, check = FALSE, ...)
```

Arguments

```
global.model, beta, evaluate, rank
see dredge.

fixed, m.lim, m.max, m.min, subset, varying, extra, ct.args, ...
see dredge.

trace displays the generated calls, but may not work as expected since the models are evaluated in batches rather than one by one.

cluster either a valid "cluster" object, or NA for a single threaded execution.

check either integer or logical value controlling how much checking for existence and correctness of dependencies is done on the cluster nodes. See 'Details'.
```

Details

All the dependencies for fitting the global.model, including the data and any objects the modelling function will use must be exported into the cluster worker nodes (e.g. *via* clusterExport). The required packages must be also loaded thereinto (e.g. *via* clusterEvalQ(...,library(package)), before the cluster is used by pdredge.

If check is TRUE or positive, pdredge tries to check whether all the variables and functions used in the call to global.model are present in the cluster nodes'. GlobalEnv before proceeding further. This causes false errors if some arguments of the model call (other than subset) would be evaluated in data environment. In that case using check = FALSE (the default) is desirable.

If check is TRUE or greater than one, pdredge will compare the global.model updated at the cluster nodes with the one given as argument.

Value

See dredge.

plot.model.selection Visualize model selection table

Description

Produces a graphical representation of model weights per model term.

Usage

```
## S3 method for class 'model.selection'
plot(x, ylab = NULL, xlab = NULL,
    labels = attr(x, "terms"), labAsExpr = FALSE,
    col = c("SlateGray", "SlateGray2"), col2 = "white", border = par("col"),
    par.lab = NULL, par.vlab = NULL,
    axes = TRUE, ann = TRUE, ...)
```

Arguments

x a "model.selection" object.
 xlab, ylab labels for the x and y axis.
 labels optional, a character vector or an expression containing model term labels (to appear on top side of the plot). Its length must be equal to number of model terms in the table. Defaults to model term names.

46 predict.averaging

labAsExpr a logical indicating whether the character labels should be interpreted (parsed)

as R expressions.

col, col2 vector of colors for columns (if more than one col is given, columns will be

filled with alternating colors). If col2 is specified cells will be filled with gradi-

ent from col to col2. Set col2 to NA for no gradient.

border border color for cells and axes.

par.lab, par.vlab

optional lists or parameters for term labels (top axis) and model names (right

axis), respectively.

axes, ann logical values indicating whether the axis and annotation should appear on the

plot.

... further graphical parameters to be set for the plot (see par).

predict.averaging

Predict method for averaged models

Description

Model-averaged predictions, optionally with standard errors.

Usage

```
## S3 method for class 'averaging'
predict(object, newdata = NULL, se.fit = FALSE,
   interval = NULL, type = NA, backtransform = FALSE, full = TRUE, ...)
```

Arguments

object an object returned by model.avg.

newdata optional data. frame in which to look for variables with which to predict. If

omitted, the fitted values are used.

se.fit logical, indicates if standard errors should be returned. This has any effect only

if the predict methods for each of the component models support it.

interval currently not used.

predict.averaging 47

type the type of predictions to return (see documentation for predict appropriate for

the class of used component models). If omitted, the default type is used. See

'Details'.

backtransform if TRUE, the averaged predictions are back-transformed from link scale to re-

sponse scale. This makes sense provided that all component models use the same family, and the prediction from each of the component models is calculated on the link scale (as specified by type. For glm, use type = "link"). See

'Details'.

full if TRUE, the full model-averaged coefficients are used (only if se.fit = FALSE

and the component objects are a result of 1m).

... arguments to be passed to respective predict method (e.g. level for lme

model).

Details

predicting is possible only with averaging objects with "modelList" attribute, i.e. those created *via* model.avg from a model list, or from model.selection object with argument fit = TRUE (which will recreate the model objects, see model.avg).

If all the component models are ordinary linear models, the prediction can be made either with the full averaged coefficients (the argument full = TRUE this is the default) or subset-averaged coefficients. Otherwise the prediction is obtained by calling predict on each component model and weighted averaging the results, which corresponds to the assumption that all predictors are present in all models, but those not estimated are equal zero (see 'Note' in model.avg). Predictions from component models with standard errors are passed to par.avg and averaged in the same way as the coefficients are.

Predictions on the response scale from generalized models can be calculated by averaging predictions of each model on the link scale, followed by inverse transformation (this is achieved with type = "link" and backtransform = TRUE). This is only possible if all component models use the same family and link function. Alternatively, predictions from each model on response scale may be averaged (with type = "response" and backtransform = FALSE). Note that this leads to results differing from those calculated with the former method. See also predict.glm.

Value

If se.fit = FALSE, a vector of predictions, otherwise a list with components: fit containing the predictions, and se.fit with the estimated standard errors.

Note

This method relies on availability of the predict methods for the component model classes (except when all component models are of class lm).

The package **MuMIn** includes predict methods for lme, and gls that calculate standard errors of the predictions (with se.fit = TRUE). They enhance the original predict methods from package **nlme**, and with se.fit = FALSE they return identical result. **MuMIn**'s versions are always used in averaged model predictions (so it is possible to predict with standard errors), but from within global environment they will be found only if **MuMIn** is before **nlme** on the search list (or directly extracted from namespace as MuMIn:::predict.lme).

QAIC

Quasi AIC or AICc

Description

Calculate a modification of Akaike's Information Criterion for overdispersed count data (or its version corrected for small sample, "quasi-AIC_c"), for one or several fitted model objects.

Usage

```
QAIC(object, ..., chat, k = 2, REML = NULL)
QAICc(object, ..., chat, k = 2, REML = NULL)
```

Arguments

object a fitted model object.

. . . optionally, more fitted model objects.

chat \hat{c} , the variance inflation factor. k the 'penalty' per parameter.

REML optional logical value, passed to the logLik method indicating whether the re-

stricted log-likelihood or log-likelihood should be used. The default is to use the

method used for model estimation.

Value

If only one object is provided, returns a numeric value with the corresponding QAIC or $QAIC_c$; otherwise returns a data. frame with rows corresponding to the objects.

Note

 \hat{c} is the dispersion parameter estimated from the global model, and can be calculated by dividing model's deviance by the number of residual degrees of freedom.

In calculation of QAIC, the number of model parameters is increased by 1 to account for estimating the overdispersion parameter. Without overdispersion, $\hat{c}=1$ and QAIC is equal to AIC.

Note that glm does not compute maximum-likelihood estimates in models within the *quasi*-family. In case it is justified, it can be worked around by 'borrowing' the aic element from the corresponding 'non-quasi' family (see 'Example').

Consider using negative. binomial family models for overdispersed count data.

50 QIC

# ML estimation
hacked.quasibinomial <- function(...) {</pre>
   res <- quasibinomial(...)</pre>
    res$aic <- binomial(...)$aic</pre>
QAIC(update(budworm.lg, family = hacked.quasibinomial), chat = chat)
## End(Not run)
```

QIC

QIC and quasi-Likelihood for GEE

Description

Calculate quasi-likelihood under the independence model criterion (QIC) for Generalized Estimating Equations.

QIC 51

Usage

```
QIC(object, ..., typeR = FALSE)
QICu(object, ..., typeR = FALSE)
quasiLik(object, ...)
```

Arguments

object a fitted model object of class "gee", "geepack", "geem", "wgee", or "yags".

for QIC and QIC_u , optionally more fitted model objects.

typeR logical, whether to calculate QIC(R). QIC(R) is based on quasi-likelihood of a

working correlation R model. Defaults to FALSE, and QIC(I) based on indepen-

dence model is returned.

Value

If just one object is provided, returns a numeric value with the corresponding QIC; if more than one object are provided, returns a data. frame with rows corresponding to the objects and one column representing QIC or QIC_u .

Note

This implementation is based partly on (revised) code from packages yags (R-Forge) and ape.

r.squaredGLMM

Pseudo-R-squared for Generalized Mixed-Effect models

Description

Calculate conditional and marginal coefficient of determination for Generalized mixed-effect models (R^2_{GLMM}) .

Usage

```
r.squaredGLMM(object, null, ...)
## S3 method for class 'merMod'
r.squaredGLMM(object, null, envir = parent.frame(), pj2014 = FALSE, ...)
```

Arguments

object	a fitted linear model object.
null	optionally, a null model, including only random effects. See 'Details'.
envir	optionally, the environment in which the null model is to be evaluated. Defaults to the current frame. See eval.
pj2014	logical, if TRUE and object is of poisson family, the result will include R^2_{GLMM} using original formulation of Johnson (2014). This requires fitting object with an observation-level random effect term added.
	additional arguments, ignored.

r.squaredGLMM 53

Details

For mixed-effects models, R^2_{GLMM} comes in two types: marginal and conditional.

Marginal R_{GLMM}^2 represents the variance explained by the fixed effects, and is defined as:

$$R^2_{GLMM(m)} = \frac{\sigma_f^2}{\sigma_f^2 + \sigma_\alpha^2 + \sigma_\varepsilon^2}$$

Conditional R_{GLMM}^2 is interpreted as a variance explained by the entire model, including both fixed and random effects, and is calculated according to the equation:

$$R^2_{GLMM(c)} = \frac{\sigma_f^2 + \sigma_\alpha^2}{\sigma_f^2 + \sigma_\alpha^2 + \sigma_\varepsilon^2}$$

where σ_f^2 is the variance of the fixed effect components, σ_α is the variance of the random effects, and σ_ϵ^2 is the "observation-level" variance.

Three different methods are available for deriving the observation-level variance σ_{ε} : the delta method, lognormal approximation and using the trigamma function.

The delta method can be used with for all distributions and link functions, while lognormal approximation and trigamma function are limited to distributions with logarithmic link. Trigamma-estimate is recommended whenever available. Additionally, for binomial distributions, theoretical variances exist specific for each link function distribution.

Null model. Calculation of the observation-level variance involves in some cases fitting a null model containing no fixed effects other than intercept, otherwise identical to the original model (including all the random effects). When using r. squaredGLMM for several models differing only in their fixed effects, in order to avoid redundant calculations, the null model object can be passed as the argument null. Otherwise, a null model will be fitted via updating the original model. This assumes that all the variables used in the original model call have the same values as when the model was fitted. The function warns about this when fitting the null model is required. This warnings can be disabled by setting options (MuMIn.noUpdateWarning = TRUE).

Value

r.squaredGLMM returns a two-column numeric matrix, each (possibly named) row holding values for marginal and conditional R^2_{GLMM} calculated with different methods, such as "delta", "lognormal", "trigamma", or "theoretical" for models of binomial family.

Note

Important: as of **MuMIn** version 1.41.0, r. squaredGLMM returns a revised statistics based on Nakagawa et al. (2017) paper. The returned value's format also has changed (it is a matrix rather than a numeric vector as before). Pre-1.41.0 version of the function calculated the "theoretical" R_{GLMM}^2 for binomial models.

 R^2_{GLMM} can be calculated also for fixed-effect models. In the simpliest case of OLS it reduces to var(fitted) / (var(fitted) + deviance / 2). Unlike likelihood-ratio based R^2 for OLS, value of this statistic differs from that of the classical R^2 .

54 r.squaredGLMM

Currently methods exist for classes: merMod, lme, glmmTMB, glmmADMB, glmmPQL, cpglm(m) and (g)lm.

See note in r. squaredLR help page for comment on using \mathbb{R}^2 in model selection.

Author(s)

Kamil Bartoń. This implementation is based on R code from 'Supporting Information' for Nakagawa et al. (2014), (the extension for random-slopes) Johnson (2014), and includes developments from Nakagawa et al. (2017).

r.squaredLR

Likelihood-ratio based pseudo-R-squared

Description

Calculate a coefficient of determination based on the likelihood-ratio test (R_{LR}^2) .

Usage

```
r.squaredLR(object, null = NULL, null.RE = FALSE, ...)
null.fit(object, evaluate = FALSE, RE.keep = FALSE, envir = NULL, ...)
```

Arguments

object	a fitted model object.
null	a fitted <i>null</i> model. If not provided, null.fit will be used to construct it. null.fit's capabilities are limited to only a few model classes, for others the <i>null</i> model has to be specified manually.
null.RE	logical, should the null model contain random factors? Only used if no $null$ model is given, otherwise omitted, with a warning.
evaluate	if TRUE evaluate the fitted model object else return the call.
RE.keep	if TRUE, the random effects of the original model are included.
envir	the environment in which the $null$ model is to be evaluated, defaults to the environment of the original model's formula.
•••	further arguments, of which only x would be used, to maintain compatibility with older versions (x has been replaced with object).

Details

This statistic is is one of the several proposed pseudo- R^2 's for nonlinear regression models. It is based on an improvement from null (intercept only) model to the fitted model, and calculated as

$$R_{LR}^2 = 1 - \exp(-\frac{2}{n}(\log \mathcal{L}(x) - \log \mathcal{L}(0)))$$

where $\log \mathcal{L}(x)$ and $\log \mathcal{L}(0)$ are the log-likelihoods of the fitted and the *null* model respectively. ML estimates are used if models have been fitted by REstricted ML (by calling logLik with argument

56 stacking Weights

REML = FALSE). Note that the *null* model can include the random factors of the original model, in which case the statistic represents the 'variance explained' by fixed effects.

For OLS models the value is consistent with classical R^2 . In some cases (e.g. in logistic regression), the maximum R_{LR}^2 is less than one. The modification proposed by Nagelkerke (1991) adjusts the R_{LR}^2 to achieve 1 at its maximum: $\bar{R}^2 = R_{LR}^2/\max(R_{LR}^2)$ where $\max(R_{LR}^2) = 1 - \exp(\frac{2}{n}\log\mathcal{L}(0))$.

null. fit tries to guess the *null* model call, given the provided fitted model object. This would be usually a glm. The function will give an error for an unrecognised class.

Value

r.squaredLR returns a value of R_{LR}^2 , and the attribute "adj.r.squared" gives the Nagelkerke's modified statistic. Note that this is not the same as nor equivalent to the classical 'adjusted R squared'.

null.fit returns the fitted *null* model object (if evaluate = TRUE) or an unevaluated call to fit a *null* model.

Note

 R^2 is a useful goodness-of-fit measure as it has the interpretation of the proportion of the variance 'explained', but it performs poorly in model selection, and is not suitable for use in the same way as the information criteria.

stackingWeights

Stacking model weights

Description

Computes model weights based on a cross-validation-like procedure.

Usage

```
stackingWeights(object, ..., data, R, p = 0.5)
```

stacking Weights 57

Arguments

object,	two or more fitted glm objects, or a list of such, or an "averaging" object.
data	a data frame containing the variables in the model, used for fitting and prediction.
R	the number of replicates.
р	the proportion of the data to be used as training set. Defaults to 0.5.

Details

Each model in a set is fitted to the training data: a subset of p * N observations in data. From these models a prediction is produced on the remaining part of data (the test or hold-out data). These hold-out predictions are fitted to the hold-out observations, by optimising the weights by which the models are combined. This process is repeated R times, yielding a distribution of weights for each model (which Smyth & Wolpert (1998) referred to as an 'empirical Bayesian estimate of posterior model probability'). A mean or median of model weights for each model is taken and re-scaled to sum to one.

Value

stackingWeights returns a matrix with two rows, holding model weights calculated using mean and median.

Note

This approach requires a sample size of at least $2\times$ the number of models.

std.coef

Standardized model coefficients

Description

Standardize model coefficients by Standard Deviation or Partial Standard Deviation.

Usage

```
std.coef(x, partial.sd, ...)
partial.sd(x)

# Deprecated:
beta.weights(model)
```

Arguments

x, model a fitted model object.

partial.sd logical, if set to TRUE, model coefficients are multiplied by partial SD, otherwise

they are multiplied by the ratio of the standard deviations of the independent

variable and dependent variable.

... additional arguments passed to coefTable, e.g. dispersion.

Details

Standardizing model coefficients has the same effect as centring and scaling the input variables. "Classical" standardized coefficients are calculated as $\beta_i^* = \beta_i \frac{s_{X_i}}{s_y}$, where β is the unstandardized coefficient, s_{X_i} is the standard deviation of associated dependent variable X_i and s_y is SD of the response variable.

If variables are intercorrelated, the standard deviation of X_i used in computing the standardized coefficients β_i^* should be replaced by the partial standard deviation of X_i which is adjusted for the multiple correlation of X_i with the other X variables included in the regression equation. The partial standard deviation is calculated as $s_{X_i}^* = s_{X_i} VIF(X_i)^{-0.5} (\frac{n-1}{n-p})^{0.5}$, where VIF is the variance inflation factor, n is the number of observations and p, the number of predictors in the model. The coefficient is then transformed as $\beta_i^* = \beta_i s_{X_i}^*$.

std.coef 59

Value

A matrix with at least two columns for the standardized coefficient estimate and its standard error. Optionally, the third column holds degrees of freedom associated with the coefficients.

Author(s)

Kamil Bartoń. Variance inflation factors calculation is based on function vif from package **car** written by Henric Nilsson and John Fox.

stdize

Standardize data

Description

stdize standardizes variables by centring and scaling. stdizeFit modifies a model call or existing model to use standardized variables.

Usage

```
## Default S3 method:
stdize(x, center = TRUE, scale = TRUE, ...)
## S3 method for class 'logical'
stdize(x, binary = c("center", "scale", "binary", "half", "omit"),
    center = TRUE, scale = FALSE, ...)
## also for two-level factors
## S3 method for class 'data.frame'
stdize(x, binary = c("center", "scale", "binary", "half", "omit"),
    center = TRUE, scale = TRUE, omit.cols = NULL, source = NULL,
   prefix = TRUE, append = FALSE, ...)
## S3 method for class 'formula'
stdize(x, data = NULL, response = FALSE,
   binary = c("center", "scale", "binary", "half", "omit"),
   center = TRUE, scale = TRUE, omit.cols = NULL, prefix = TRUE,
    append = FALSE, ...)
stdizeFit(object, data, which = c("formula", "subset", "offset", "weights"),
    evaluate = TRUE, quote = NA)
```

Arguments

x center, scale

binary

a numeric or logical vector, factor, numeric matrix, data. frame or a formula. either a logical value or a logical or numeric vector of length equal to the number of columns of x (see 'Details'). scale can be also a function to use for scaling. specifies how binary variables (logical or two-level factors) are scaled. Default is to "center" by subtracting the mean assuming levels are equal to 0 and 1; use "scale" to both centre and scale by SD, "binary" to centre to 0/1, "half" to centre to -0.5 / 0.5, and "omit" to leave binary variables unmodified. This argument has precedence over center and scale, unless it is set to NA (in which case binary variables are treated like numeric variables).

stdize 61

source	a reference data.frame, being a result of previous stdize, from which scale and center values are taken. Column names are matched. This can be used for scaling new data using statistics of another data.
omit.cols	column names or numeric indices of columns that should be left unaltered.
prefix	either a logical value specifying whether the names of transformed columns should be prefixed, or a two-element character vector giving the prefixes. The prefixes default to "z." for scaled and "c." for centred variables.
append	logical, if TRUE, modified columns are appended to the original data frame.
response	logical, stating whether the response should be standardized. By default, only variables on the right-hand side of the formula are standardized.
data	an object coercible to data. frame, containing the variables in formula. Passed to, and used by model. frame.
	For stdizeFit, a stdized data.frame to use.
	for the formula method, additional arguments passed to model.frame. For other methods, it is silently ignored.
object	a fitted model object or an expression being a call to the modelling function.
which	a character string naming arguments which should be modified. This should be all arguments which are evaluated in the data environment. Can be also TRUE to modify the expression as a whole. The data argument is additionally replaced with that passed to stdizeFit.
evaluate	if TRUE, the modified call is evaluated and the fitted model object is returned.
quote	if TRUE, avoids evaluating object. Equivalent to stdizeFit(quote(expr),). Defaults to NA in which case object being a call to non-primitive function is quoted.

Details

stdize resembles scale, but uses special rules for factors, similarly to standardize in package arm

stdize differs from standardize in that it is used on data rather than on the fitted model object. The scaled data should afterwards be passed to the modelling function, instead of the original data.

Unlike standardize, it applies special 'binary' scaling only to two-level factors and logical variables, rather than to any variable with two unique values.

Variables of only one unique value are unchanged.

By default, stdize scales by dividing by standard deviation rather than twice the SD as standardize does. Scaling by SD is used also on uncentred values, which is different from scale where root-mean-square is used.

If center or scale are logical scalars or vectors of length equal to the number of columns of x, the centring is done by subtracting the mean (if center corresponding to the column is TRUE), and scaling is done by dividing the (centred) value by standard deviation (if corresponding scale is TRUE). If center or scale are numeric vectors with length equal to the number of columns of x (or numeric scalars for vector methods), then these are used instead. Any NAs in the numeric vector result in no centring or scaling on the corresponding column.

Note that scale = 0 is equivalent to no scaling (i.e. scale = 1).

62 stdize

Binary variables, logical or factors with two levels, are converted to numeric variables and transformed according to the argument binary, unless center or scale are explicitly given.

Value

stdize returns a vector or object of the same dimensions as x, where the values are centred and/or scaled. Transformation is carried out column-wise in data. frames and matrices.

The returned value is compatible with that of scale in that the numeric centring and scalings used are stored in attributes "scaled:center" and "scaled:scale" (these can be NA if no centring or scaling has been done).

stdizeFit returns a modified, unevaluated call where the variable names are replaced to point the transformed variables, or if evaluate is TRUE, a fitted model object.

subset.model.selection

Subsetting model selection table

Description

Extract a subset of a model selection table.

Usage

```
## S3 method for class 'model.selection'
```

64 subset.model.selection

```
subset(x, subset, select, recalc.weights = TRUE, recalc.delta = FALSE, ...)
## S3 method for class 'model.selection'
x[i, j, recalc.weights = TRUE, recalc.delta = FALSE, ...]
## S3 method for class 'model.selection'
x[[..., exact = TRUE]]
```

Arguments

x a model.selection object to be subsetted. subset, select logical expressions indicating columns and rows to keep. See subset. i, j indices specifying elements to extract. recalc.weights logical value specyfying whether Akaike weights should be normalized across the new set of models to sum to one. recalc.delta logical value specyfying whether Δ_{IC} should be calculated for the new set of models (not done by default). exact logical, see [. further arguments passed to [.data.frame (drop).

Details

Unlike the method for data. frame, single bracket extraction with only one index x[i] selects rows (models) rather than columns.

To select rows according to presence or absence of the variables (rather than their value), a pseudofunction has may be used with subset, e.g. subset(x,has(a,!b)) will select rows with a and without b (this is equivalent to !is.na(a) & is.na(b)). has can take any number of arguments.

Complex model terms need to be enclosed within curly brackets (e.g {s(a,k=2)}), except for within has. Backticks-quoting is also possible, but then the name must match exactly (including whitespace) the term name as returned by getAllTerms.

Enclosing in I prevents the name from being interpreted as a column name.

To select rows where one variable can be present conditional on the presence of other variables, the function dc (dependency chain) can be used. dc takes any number of variables as arguments, and allows a variable to be included only if all the preceding arguments are also included (e.g. subset = dc(a,b,c) allows for models of form a, a+b and a+b+c but not b, c, b+c or a+c).

Value

A model.selection object containing only the selected models (rows). If columns are selected (via argument select or the second index x[,j]) and not all essential columns (i.e. all except "varying" and "extra") are present in the result, a plain data.frame is returned. Similarly, modifying values in the essential columns with [<-, [[<- or <- produces a regular data frame.]]

# This gives a different result than previous command, because 'subset' is
# applied to the original selection table that is ranked with 'AICc'
sw(model.avg(ms1, rank = AIC, rank.args = list(k = lognobs),
    subset = cumsum(weight) <= .95))</pre>
```

updateable

Make a function return updateable result

Description

Creates a function wrapper that stores a call in the object returned by its argument FUN.

updateable 67

Usage

```
updateable(FUN, eval.args = NULL, Class)
get_call(x)
## updateable wrapper for mgcv::gamm and gamm4::gamm4
uGamm(formula, random = NULL, ..., lme4 = inherits(random, "formula"))
```

Arguments

FUN function to be modified, found *via* match. fun.

eval.args optionally a character vector of function arguments' names to be evaluated in

the stored call. See 'Details'.

Class optional character vector naming class(es) to be set onto the result of FUN (not

possible with formal S4 objects).

x an object from which the call should be extracted.

formula, random, ...

arguments to be passed to gamm or gamm4

lme4 if TRUE, gamm4 is called, gamm otherwise.

Details

Most model fitting functions in R return an object that can be updated or re-fitted *via* update. This is thanks to the call stored in the object, which can be used (possibly modified) later on. It is also utilised by dredge to generate sub-models. Some functions (such as gamm or MCMCglmm) do not provide their result with the call element. To work that around, updateable can be used on that function to store the call. The resulting "wrapper" should be used in exactly the same way as the original function.

Argument eval.args specifies names of function arguments that should be evaluated in the stored call. This is useful when, for example, the model object does not have formula element. The default formula method tries to retrieve formula from the stored call, which works unless the formula has been given as a variable and value of that variable changed since the model was fitted (the last 'example' demonstrates this).

Value

updateable returns a function with the same arguments as FUN, wrapping a call to FUN and adding an element named call to its result if possible, otherwise an attribute "call" (if the returned value is atomic or a formal S4 object).

Note

get_call is similar to getCall (defined in package stats), but it can also extract the call when it is an attribute (and not an element of the object). Because the default getCall method cannot do that, the default update method will not work with atomic or S4 objects resulting from updateable wrappers.

68 updateable

uGamm sets also an appropriate class onto the result ("gamm4" and/or "gamm"), which is needed for some generics defined in **MuMIn** to work (note that unlike the functions created by updateable it has no formal arguments of the original function). As of version 1.9.2, MuMIn::gamm is no longer available.

Weights

Akaike weights

Description

Calculate, extract or set normalized model likelihoods ('Akaike weights').

Usage

```
Weights(x)
Weights(x) <- value</pre>
```

70 Weights

Arguments

Χ	a numeric vector of information criterion values such as AIC, or objects returned
	by functions like AIC. There are also methods for extracting 'Akaike weights'
	from "model.selection" or "averaging" objects.
value	numeric, the new weights for the "averaging" object or NULL to reset the weights based on the original IC used.

Details

The replacement function can assign new weights to an "averaging" object, affecting coefficient values and order of component models.

Value

For the extractor, a numeric vector of normalized likelihoods.

Note

On assigning new weights, the model order changes accordingly, so assigning the same weights again will cause incorrect re-calculation of averaged coefficients. To avoid that, either re-set model weights by assigning NULL, or use ordered weights.
