# Package 'R2BayesX'

December 5, 2017
Version 1.1-1
Date 2017-12-05
Title Estimate Structured Additive Regression Models with 'BayesX'
<b>Description</b> An R interface to estimate structured additive regression (STAR) models with 'BayesX'.
<b>Depends</b> R (>= 2.13.0), BayesXsrc, colorspace, mgcv
Suggests akima, coda, maps, maptools, MBA, parallel, shapefiles, sp, spdep, splines, rgdal, spData
Imports methods
License GPL-2   GPL-3
LazyLoad yes
NeedsCompilation yes

R2BayesX-package 3

R2BayesX-package

Estimate STAR Models with BayesX

## Description

This package interfaces the **BayesX** (http://www.BayesX.org) command-line binary from R. The main model fitting function is called bayesx.

Before STAR models can be estimated, the command-line version of **BayesX** needs to be installed, which is done by installing the R source code package **BayesXsrc**. Please see function bayesx and bayesx.control for more details on model fitting and controlling.

The package also provides functionality for high level graphics of estimated effects, see function plot.bayesx, plot2d, plot3d, plotblock, plotmap, plotsamples and colorlegend.

More standard extractor functions and methods for the fitted model objects may be applied, e.g., see function summary.bayesx, fitted.bayesx, residuals.bayesx, samples, plot.bayesx, as well as AIC, BIC etc., please see the examples of the help sites. Predictions for new data based on refitting with weights can be obtained by function predict.bayesx.

In addition, it is possible to run arbitrary **BayesX** program files using function run.bayesx. **BayesX** output files that are stored in a directory may be read into R calling function read.bayesx.output.

#### Author(s)

Nikolaus Umlauf, Thomas Kneib, Stefan Lang, Achim Zeileis.

#### **Examples**

```
## to see the package demos
demo(package = "R2BayesX")
```

add.neighbor

Add Neighborhood Relations

# **Description**

Adds a neighborhhod relationship between two given regions to a map object in graph format.

# Usage

```
add.neighbor(map, region1, region2)
```

# **Arguments**

```
map map object in graph format that should be modified. region1, region2
```

character, names of the regions that should be connected as neighbors.

#### Value

Returns an adjacency matrix that represents the neighborhood structure of map plus the new neighborhood relation in graph format.

#### Author(s)

Felix Heinzl, Thomas Kneib.

#### See Also

```
get.neighbor, delete.neighbor, read.gra, write.gra, bnd2gra.
```

# **Examples**

```
## read the graph file
file <- file.path(find.package("R2BayesX"), "examples", "Germany.gra")
germany <- read.gra(file)

## add some neighbors
get.neighbor(germany, c("1001", "7339"))
germany <- add.neighbor(germany, "7339", "1001")
get.neighbor(germany, c("1001", "7339"))</pre>
```

bayesx

Estimate STAR Models with BayesX

# Description

This is the documentation of the main model fitting function of the interface. Within function bayesx, three inferential concepts are available for estimation: Markov chain Monte Carlo simulation (MCMC), estimation based on mixed model technology and restricted maximum likelihood (REML), and a penalized least squares (respectively penalized likelihood) approach for estimating models using model selection tools (STEP).

#### Usage

```
bayesx(formula, data, weights = NULL, subset = NULL,
  offset = NULL, na.action = NULL, contrasts = NULL,
  control = bayesx.control(...), model = TRUE,
  chains = NULL, cores = NULL, ...)
```

# **Arguments**

8	
formula	symbolic description of the model (of type y $\sim$ x), also see sx, formula.gam and s.
data	a data.frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from environment(formula): typically the environment from which bayesx is called. Argument data may also be a character string defining the directory the data is stored, where the first row in the data set must contain the variable names and columns should be tab separated. Using this option will avoid loading the complete data into R, only the <b>BayesX</b> output files will be imported, which might be helpful using large datasets.
weights	prior weights on the data.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
offset	can be used to supply a model offset for use in fitting.
na.action	a function which indicates what should happen when the data contain NA's. The default is set by the na.action setting of options, and is na.omit if set to NULL.
contrasts	an optional list. See the contrasts.arg of model.matrix.default.
control	specify several global control parameters for bayesx, see bayesx.control.
model	a logical value indicating whether model.frame should be included as a component of the returned value.
chains	integer. The number of sequential chains that should be run, the default is one chain if chains = NULL. For each chain a separate seed for the random number generator is used. The return value of bayesx is a list of class "bayesx", i.e. each list element represents a seperate model, for which the user can e.g. apply all plotting methods or extractor functions. Convergence diagnostics can then be computed using function GRstats.
cores	integer. How many cores should be used? The default is one core if cores = NULL. The return value is again a list of class "bayesx", for which all plotting and extractor functions can be applied, see argument chains. Note that this option is not available on Windows systems, see the documentation of function mclapply.
	arguments passed to <pre>bayesx.control</pre> , e.g. family and method, defaults are family = "gaussian", method = "MCMC".

# **Details**

In BayesX, estimation of regression parameters is based on three inferential concepts:

**Full Bayesian inference via MCMC**: A fully Bayesian interpretation of structured additive regression models is obtained by specifying prior distributions for all unknown parameters. Estimation can be facilitated using Markov chain Monte Carlo simulation techniques. **BayesX** provides numerically efficient implementations of MCMC schemes for structured additive regression models. Suitable proposal densities have been developed to obtain rapidly mixing, well-behaved sampling schemes without the need for manual tuning.

Inference via a mixed model representation: The other concept used for estimation is based on mixed model methodology. Within BayesX this concept has been extended to structured additive regression models and several types of non-standard regression situations. The general idea is to take advantage of the close connection between penalty concepts and corresponding random effects distributions. The smoothing parameters of the penalties then transform to variance components in the random effects (mixed) model. While the selection of smoothing parameters has been a difficult task for a long time, several estimation procedures for variance components in mixed models are already available since the 1970's. The most popular one is restricted maximum likelihood in Gaussian mixed models with marginal likelihood as the non-Gaussian counterpart. While regression coefficients are estimated based on penalized likelihood, restricted maximum likelihood or marginal likelihood estimation forms the basis for the determination of smoothing parameters. From a Bayesian perspective, this yields empirical Bayes/posterior mode estimates for the structured additive regression models. However, estimates can also merely be interpreted as penalized likelihood estimates from a frequentist perspective.

**Penalized likelihood including variable selection**: As a third alternative **BayesX** provides a penalized least squares (respectively penalized likelihood) approach for estimating structured additive regression models. In addition, a powerful variable and model selection tool is included. Model choice and estimation of the parameters is done simultaneously. The algorithms are able to

- decide whether a particular covariate enters the model,
- decide whether a continuous covariate enters the model linearly or nonlinearly,
- decide whether a spatial effect enters the model,
- decide whether a unit- or cluster specific heterogeneity effect enters the model
- select complex interaction effects (two dimensional surfaces, varying coefficient terms)
- select the degree of smoothness of nonlinear covariate, spatial or cluster specific heterogeneity effects.

Inference is based on penalized likelihood in combination with fast algorithms for selecting relevant covariates and model terms. Different models are compared via various goodness of fit criteria, e.g. AIC, BIC, GCV and 5 or 10 fold cross validation.

Within the model fitting function bayesx, the different inferential concepts may be chosen by argument method of function bayesx.control. Options are "MCMC", "REML" and "STEP".

The wrapper function bayesx basically starts by setting up the necessary **BayesX** program file using function bayesx.construct, parse.bayesx.input and write.bayesx.input. Afterwards the generated program file is send to the command-line binary executable version of **BayesX** with run.bayesx. As a last step, function read.bayesx.output will read the estimated model object returned from **BayesX** back into R.

For estimation of STAR models, function bayesx uses formula syntax as provided in package mgcv (see formula.gam), i.e., models may be specified using the R2BayesX main model term constructor functions sx or the mgcv constructor functions s. For a detailed description of the model formula syntax used within bayesx models see also bayesx.construct and bayesx.term.options.

After the **BayesX** binary has successfully finished processing an object of class "bayesx" is returned, wherefore a set of standard extractor functions and methods is available, including methods to the generic functions print, summary, plot, residuals and fitted.

See fitted.bayesx, plot.bayesx, and summary.bayesx for more details on these methods.

#### Value

A list of class "bayesx", see function read.bayesx.output.

#### WARNINGS

For geographical effects, note that **BayesX** may crash if the region identification covariate is a factor, it is recommended to code these variables as integer, please see the example below.

#### Note

If a model is specified with a structured and an unstructured spatial effect, e.g. the model formula is something like  $y \sim sx(id, bs = "mrf", map = MapBnd) + sx(id, bs = "re")$ , the model output contains of one additional total spatial effect, named with "sx(id):total". Also see the last example.

bayesx.construct

Construct BayesX Model Term Objects

# Description

The function bayesx.construct is used to provide a flexible framework to implement new model term objects in bayesx within the **BayesX** syntax.

# Usage

```
bayesx.construct(object, dir, prg, data)
```

#### **Arguments**

object is a smooth, shrinkage or random specification object in a STAR formula, generated by the R2BayesX model term constructor functions sx (or using the constructor functions s and te of the mgcv package). Objects generated by these functions have class "xx.smooth.spec" where "xx" is determined by the "bs" argument of sx (and s). character, a directory where possible data should be stored, e.g. in bayesx dir models, if bs = "gk", bs = "gs" or bs = "mrf" is choosen, the corresponding map will be written as a "bnd" or "gra" file (see read.bnd and read.gra) to this directory, so **BayesX** can use this spatial object for estimation. if additional data handling must be applied, e.g. storing maps ("bnd") objects prg in the directory specified in dir, write.bayesx.input needs to write the extra commands in a program file provided with argument prg, i.e. this may all be handled within a bayesx.construct constructor function. data if additional data is needed to setup the **BayesX** term it is found here.

#### **Details**

The main idea of these constructor functions is to provide a flexible framework to implement new model term objects in the <code>BayesX</code> syntax within <code>bayesx</code>, i.e. for any smooth or random term in <code>R2BayesX</code> a constructor function like <code>bayesx.construct.ps.smooth.construct</code> may be provided to translate R specific syntax into <code>BayesX</code> readable commands. During processing with <code>write.bayesx.input</code> each model term is constructed with <code>bayesx.construct</code> after another, wrapped into a full formula, which may then be send to the <code>BayesX</code> binary with function <code>run.bayesx</code>.

At the moment the following model terms are implemented:

- "rw1", "rw2": Zero degree P-splines: Defines a zero degree P-spline with first or second order difference penalty. A zero degree P-spline typically estimates for every distinct covariate value in the dataset a separate parameter. Usually there is no reason to prefer zero degree P-splines over higher order P-splines. An exception are ordinal covariates or continuous covariates with only a small number of different values. For ordinal covariates higher order P-splines are not meaningful while zero degree P-splines might be an alternative to modeling nonlinear relationships via a dummy approach with completely unrestricted regression parameters.
- "season": Seasonal effect of a time scale.
- "ps", "psplinerw1", "psplinerw2": P-spline with first or second order difference penalty.
- "te", "pspline2dimrw1": Defines a two-dimensional P-spline based on the tensor product of one-dimensional P-splines with a two-dimensional first order random walk penalty for the parameters of the spline.
- "kr", "kriging": Kriging with stationary Gaussian random fields.
- "gk", "geokriging": Geokriging with stationary Gaussian random fields: Estimation is based on the centroids of a map object provided in boundary format (see function read.bnd and shp2bnd) as an additional argument named map within function sx, or supplied within argument xt when using function s, e.g., xt = list(map = MapBnd).

"gs", "geospline": Geosplines based on two-dimensional P-splines with a two-dimensional
first order random walk penalty for the parameters of the spline. Estimation is based on the
coordinates of the centroids of the regions of a map object provided in boundary format (see
function read.bnd and shp2bnd) as an additional argument named map (see above).

- "mrf", "spatial": Markov random fields: Defines a Markov random field prior for a spatial covariate, where geographical information is provided by a map object in boundary or graph file format (see function read.bnd, read.gra and shp2bnd), as an additional argument named map (see above).
- "b1", "baseline": Nonlinear baseline effect in hazard regression or multi-state models: Defines a P-spline with second order random walk penalty for the parameters of the spline for the log-baseline effect  $log(\lambda(time))$ .
- "factor": Special **BayesX** specifier for factors, especially meaningful if method = "STEP", since the factor term is then treated as a full term, which is either included or removed from the model.
- "ridge", "lasso", "nigmix": Shrinkage of fixed effects: defines a shrinkage-prior for the corresponding parameters  $\gamma_j$ ,  $j=1,\ldots,q,$   $q\geq 1$  of the linear effects  $x_1,\ldots,x_q$ . There are three priors possible: ridge-, lasso- and Normal Mixture of inverse Gamma prior.
- "re": Gaussian i.i.d.\ Random effects of a unit or cluster identification covariate.

See function sx for a description of the main R2BayesX model term constructor functions.

#### Value

The model term syntax used within **BayesX** as a character string.

#### WARNINGS

If new bayesx.construct functions are implemented in future work, there may occur problems with reading the corresponding **BayesX** output files with read.bayesx.output, e.g., if the new objects do not have the structure as implemented with bs = "ps" etc., i.e. function read.bayesx.output must also be adapted in such cases.

#### Note

Using sx additional controlling arguments may be supplied within the dot dot dot "..." argument. Please see the help site for function bayesx.term.options for a detailed description of possible optional parameters.

Within the xt argument in function s, additional **BayesX** specific parameters may be also supplied, see the examples below.

```

bayesx.control

Control Parameters for BayesX

# **Description**

Various parameters that control fitting of regression models using bayesx.

#### Usage

```
bayesx.control(model.name = "bayesx.estim",
  family = "gaussian", method = "MCMC", verbose = FALSE,
  dir.rm = TRUE, outfile = NULL, replace = FALSE, iterations = 12000L,
  burnin = 2000L, maxint = NULL, step = 10L, predict = TRUE,
  seed = NULL, hyp.prior = NULL, distopt = NULL, reference = NULL,
  zipdistopt = NULL, begin = NULL, level = NULL, eps = 1e-05,
  lowerlim = 0.001, maxit = 400L, maxchange = 1e+06, leftint = NULL,
  lefttrunc = NULL, state = NULL, algorithm = NULL, criterion = NULL,
  proportion = NULL, startmodel = NULL, trace = NULL,
  steps = NULL, CI = NULL, bootstrapsamples = NULL, ...)
```

#### **Arguments**

```
character, specify a base name model output files are named with in outfile.

character, specify the distribution used for the model, options for all methods,

"MCMC", "REML" and "STEP" are: "binomial", "binomialprobit", "gamma",

"gaussian", "multinomial", "poisson". For "MCMC" and "REML" only: "cox",

"cumprobit" and "multistate". For "REML" only use: "binomialcomploglog",

"cumlogit", "multinomialcatsp", "multinomialprobit", "seqlogit", "seqprobit".

method character, which method should be used for estimation, options are "MCMC",

"HMCMC" (hierarchical MCMC), "REML" and "STEP".
```

verbose logical, should output be printed to the R console during runtime of bayesx. dir.rm logical, should the the output files and directory removed after estimation? outfile character, specify a directory where bayesx should store all output files, all output files will be named with model. name as the base name.

if set to TRUE, the files in the output directory specified in argument outfile

will be replaced.

iterations integer, sets the number of iterations for the sampler.

burnin integer, sets the burn-in period of the sampler.

> integer, if first or second order random walk priors are specified, in some cases the data will be slightly grouped: The range between the minimal and maximal observed covariate values will be divided into (small) intervals, and for each interval one parameter will be estimated. The grouping has almost no effect on estimation results as long as the number of intervals is large enough. With the maxint option the amount of grouping can be determined by the user. integer is the maximum number of intervals allowed. for equidistant data, the default maxint = 150 for example, means that no grouping will be done as long as the number of different observations is equal to or below 150. for non equidistant data some grouping may be done even if the number of different observations is

below 150.

integer, defines the thinning parameter for MCMC simulation. E.g., step = 50 means, that only every 50th sampled parameter will be stored and used to compute characteristics of the posterior distribution as means, standard deviations or quantiles. The aim of thinning is to reach a considerable reduction of disk storing and autocorrelations between sampled parameters.

logical, option predict may be specified to compute samples of the deviance D, the effective number of parameters pD and the deviance information crite-

rion DIC of the model. In addition, if predict = FALSE, only output files of estimated effects will be returned, otherwise an expanded dataset using all observations would be written in the output directory, also containing the data used for estimation. Hence, this option is useful when dealing with large data sets,

that might cause memory problems if predict is set to TRUE.

integer, set the seed of the random number generator in BayesX, usually set

using function set. seed.

numeric, defines the value of the hyper-parameters a and b for the inverse gamma

prior of the overall variance parameter  $\sigma^2$ , if the response distribution is Gaussian. numeric, must be a positive real valued number. The default is hyp.prior = c(1, 0.005).

character, defines the implemented formulation for the negative binomial model if the response distribution is negative binomial. The two possibilities are to

work with a negative binomial likelihood (distopt = "nb") or to work with the Poisson likelihood and the multiplicative random effects (distopt = "poga").

character, option reference is meaningful only if either family = "multinomial"

or family = "multinomialprobit" is specified as the response distribution. In this case reference defines the reference category to be chosen. Suppose, for instance, that the response is three categorical with categories 1, 2 and 3.

Then reference = 2 defines the value 2 to be the reference category.

step

replace

maxint

predict

seed

hyp.prior

distopt

reference

zipdistopt character, defines the zero inflated distribution for the regression analysis. The

two possibilities are to work with a zero infated Poisson distribution (zipdistopt = "zip")

or to work with the zero inflated negative binomial likelihood (zipdistopt = "zinb").

begin character, option begin is meaningful only if family = "cox" is specified as the response distribution. In this case begin specifies the variable that records when the observation became at risk. This option can be used to handle left trun-

cation and time-varying covariates. If begin is not specified, all observations are

assumed to have become at risk at time 0.

integer, besides the posterior means and medians, BayesX provides point-wise posterior credible intervals for every effect in the model. In a Bayesian approach based on MCMC simulation techniques credible intervals are estimated by computing the respective quantiles of the sampled effects. By default, **BayesX** computes (point-wise) credible intervals for nominal levels of 80% and 95%. The option level[1] allows to redefine one of the nominal levels (95%). Adding, for instance, level[1] = 99 to the options list computes credible intervals for a nominal level of 99% rather than 95%. Similar to argument level[1] the op-

tion level[2] allows to redefine one of the nominal levels (80%). Adding, for instance, level[2] = 70 to the options list computes credible intervals for a

nominal level of 70% rather than 80%.

numeric, defines the termination criterion of the estimation process. If both the relative changes in the regression coefficients and the variance parameters are

less than eps, the estimation process is assumed to have converged.

numeric, since small variances are close to the boundary of their parameter space, the usual fisher-scoring algorithm for their determination has to be modified. If the fraction of the penalized part of an effect relative to the total effect is less than lowerlim, the estimation of the corresponding variance is stopped and the estimator is defined to be the current value of the variance (see section

6.2 of the BayesX methodology manual for details).

integer, defines the maximum number of iterations to be used in estimation. Since the estimation process will not necessarily converge, it may be useful to define an upper bound for the number of iterations. Note, that **BayesX** returns results based on the current values of all parameters even if no convergence could be achieved within maxit iterations, but a warning message will be printed

in the output window.

numeric, defines the maximum value that is allowed for relative changes in parameters in one iteration to prevent the program from crashing because of nu-

merical problems. Note, that BayesX produces results based on the current values of all parameters even if the estimation procedure is stopped due to numerical problems, but an error message will be printed in the output window.

character, gives the name of the variable that contains the lower (left) boundary  $T_{lo}$  of the interval  $[T_{lo}, T_{up}]$  for an interval censored observation. for right censored or uncensored observations we have to specify  $T_{lo} = T_{up}$ . If leftint is missing, all observations are assumed to be right censored or uncensored,

depending on the corresponding value of the censoring indicator.

character, option lefttrunc specifies the name of the variable containing the left truncation time  $T_{tr}$ . For observations that are not truncated, we have to

level

eps

lowerlim

maxit

maxchange

leftint

lefttrunc

specify  $T_{tr} = 0$ . If lefttrunc is missing, all observations are assumed to be not truncated. for multi-state models variable lefttrunc specifies the left endpoint of the corresponding time interval.

state

character, for multi-state models, state specifies the current state variable of the process.

algorithm

character, specifies the selection algorithm. Possible values are "cdescent1" (adaptive algorithms in the methodology manual, see subsection 6.3), "cdescent2" (adaptive algorithms 1 and 2 with backfitting, see remarks 1 and 2 of section 3 in Belitz and Lang (2008)), "cdescent3" (search according to cdescent1 followed by cdescent2 using the selected model in the first step as the start model) and "stepwise" (stepwise algorithm implemented in the gam routine of S-plus, see Chambers and Hastie, 1992). This option will rarely be specified by the user.

criterion

character, specifies the goodness of fit criterion. If criterion = "MSEP" is specified the data are randomly divided into a test- and validation data set. The test data set is used to estimate the models and the validation data set is used to estimate the mean squared prediction error (MSEP) which serves as the goodness of fit criterion to compare different models. The proportion of data used for the test and validation sample can be specified using option proportion, see below. The default is to use 75% of the data for the training sample.

proportion

numeric, this option may be used in combination with option criterion = "MSEP", see above. In this case the data are randomly divided into a training and a validation sample. proportion defines the fraction (between 0 and 1) of the original data used as training sample.

startmodel

character, defines the start model for variable selection. Options are "linear", "empty", "full" and "userdefined".

trace

character, specifies how detailed the output in the output window will be. Options are "trace\_on", "trace\_half" and "trace\_off".

steps

integer, defines the maximum number of iterations. If the selection process has not converged after steps iterations the algorithm terminates and a warning is raised. Setting steps = 0 allows the user to estimate a certain model without any model choice. This option will rarely be specified by the user.

CI

character, compute confidence intervals for linear and nonlinear terms. Option CI allows to compute confidence intervals. Options are CI = "none", confidence intervals conditional on the selected model CI = "MCMCselect" and unconditional confidence intervals where model uncertainty is taken into account CI = "MCMCbootstrap". Both alternatives are computer intensive. Conditional confidence intervals take much less computing time than unconditional intervals. The advantage of unconditional confidence intervals is that sampling distributions for the degrees of freedom or smoothing parameters are obtained.

bootstrapsamples

integer, defines the number of bootstrap samples used for "CI = MCMCbootstrap".

... not used

#### Value

A list with the arguments specified is returned.

20 bayesx.term.options

bayesx.term.options Show BayesX Term Options

# Description

**BayesX** model terms specified using functions sx may have additional optional control arguments. Therefore function bayesx.term.options displays the possible additional controlling parameters for a particular model term.

bayesx.term.options 21

# Usage

```
bayesx.term.options(bs = "ps", method = "MCMC")
```

#### **Arguments**

bs character, the term specification for which controlling parameters should be

shown.

method character, for which method should additional arguments be shown, options are

"MCMC", "REML" and "STEP".

#### **Details**

At the moment the following model terms are implemented, for which additional controlling parameters may be specified:

- "rw1", "rw2": Zero degree P-splines: Defines a zero degree P-spline with first or second order difference penalty. A zero degree P-spline typically estimates for every distinct covariate value in the dataset a separate parameter. Usually there is no reason to prefer zero degree P-splines over higher order P-splines. An exception are ordinal covariates or continuous covariates with only a small number of different values. For ordinal covariates higher order P-splines are not meaningful while zero degree P-splines might be an alternative to modeling nonlinear relationships via a dummy approach with completely unrestricted regression parameters.
- "season": Seasonal effect of a time scale.
- "ps", "psplinerw1", "psplinerw2": P-spline with first or second order difference penalty.
- "te", "pspline2dimrw1": Defines a two-dimensional P-spline based on the tensor product of one-dimensional P-splines with a two-dimensional first order random walk penalty for the parameters of the spline.
- "kr", "kriging": Kriging with stationary Gaussian random fields.
- "gk", "geokriging": Geokriging with stationary Gaussian random fields: Estimation is based on the centroids of a map object provided in boundary format (see function read.bnd and shp2bnd) as an additional argument named map within function sx, or supplied within argument xt when using function s, e.g., xt = list(map = MapBnd).
- "gs", "geospline": Geosplines based on two-dimensional P-splines with a two-dimensional first order random walk penalty for the parameters of the spline. Estimation is based on the coordinates of the centroids of the regions of a map object provided in boundary format (see function read.bnd and shp2bnd) as an additional argument named map (see above).
- "mrf", "spatial": Markov random fields: Defines a Markov random field prior for a spatial covariate, where geographical information is provided by a map object in boundary or graph file format (see function read.bnd, read.gra and shp2bnd), as an additional argument named map (see above).
- "b1", "baseline": Nonlinear baseline effect in hazard regression or multi-state models: Defines a P-spline with second order random walk penalty for the parameters of the spline for the log-baseline effect  $log(\lambda(time))$ .
- "factor": Special **BayesX** specifier for factors, especially meaningful if method = "STEP", since the factor term is then treated as a full term, which is either included or removed from the model.

22 bayesx\_logfile

• "ridge", "lasso", "nigmix": Shrinkage of fixed effects: defines a shrinkage-prior for the corresponding parameters  $\gamma_j$ ,  $j=1,\ldots,q,$   $q\geq 1$  of the linear effects  $x_1,\ldots,x_q$ . There are three priors possible: ridge-, lasso- and Normal Mixture of inverse Gamma prior.

• "re": Gaussian i.i.d. Random effects of a unit or cluster identification covariate.

BeechBnd

Beech Location Map

# **Description**

This database produces a location map of beeches around Rothenbuch, Germany.

# Usage

```
data("BeechBnd")
```

#### **Format**

A list of class "bnd" containing 83 polygon matrices with x-coordinates in the first and y-coordinates in the second column each.

# Source

```
http://www.BayesX.org.
```

#### See Also

```
plotmap, read.bnd, write.bnd

plotmap(BeechBnd)
```

26 bnd2gra

BeechGra

Beech Neighborhood Information

# Description

This database produces a graph file including neighborhood information of the beech trees around Rothenbuch, Germany.

# Usage

```
data("BeechGra")
```

#### **Format**

An adjacency matrix that represents the neighborhood structure defined in the graph file.

# Source

```
http://www.BayesX.org.
```

#### See Also

```

data("BeechGra")
print(BeechGra)
```

bnd2gra

Convert Boundary Format to Graph Format

# Description

Converts a map in boundary format to a map in graph format.

# Usage

```
bnd2gra(map, npoints = 2)
```

# **Arguments**

map in boundary format that should be converted.

npoints integer. How many points must be shared by two polygons to be a neighbor?

#### Value

Returns an adjacency matrix that represents the neighborhood structure of the map object in graph format

#### Author(s)

Felix Heinzl, Thomas Kneib.

colorlegend

Plot a Color Legend

#### **Description**

Function to generate a color legend, the legend may be added to an existing plot or drawn in a separate plotting window.

#### Usage

```
colorlegend (color = NULL, ncol = NULL, x = NULL,
  breaks = NULL, pos = "center", shift = 0.02, side.legend = 1L,
  side.ticks = 1L, range = NULL, lrange = NULL,
  width = 0.4, height = 0.06, scale = TRUE, xlim = NULL,
  ylim = NULL, plot = NULL, full = FALSE, add = FALSE,
  col.border = "black", lty.border = 1L, lwd.border = 1L,
  ticks = TRUE, at = NULL, col.ticks = "black", lwd.ticks = 1L,
  lty.ticks = 1L, length.ticks = 0.3, labels = NULL,
  distance.labels = 0.8, col.labels = "black", cex.labels = 1L,
  digits = 2L, swap = FALSE, symmetric = TRUE, xpd = NULL,
  title = NULL, side.title = 2, shift.title = c(0, 0), ...)
```

#### **Arguments**

color character, integer. The colors for the legend, may also be a function, e.g. colors = heat.colors.

ncol integer, the number of different colors that should be generated if color is a

function.

x numeric, values for which the color legend should be drawn.

breaks numeric, a set of breakpoints for the colors: must give one more breakpoint than

ncol.

pos character, numeric. The position of the legend. Either a numeric vector, e.g.

pos = c(0.1, 0.2) will add the legend at the 10% point in the x-direction and at the 20% point in the y-direction of the plotting window, may also be negative, or one of the following: "bottomleft", "topleft", "topright",

"bottomright", "left", "right", "top", "bottom" and "center".

shift numeric, if argument pos is a character, shift determines the distance of the

legend from the plotting box.

side. legend integer, if set to 2 the legend will be flipped by 90 degrees.

side.ticks integer, if set to 2, the ticks and labels will be on the opposite site of the legend.

numeric, specifies a range for x values for which the legend should be drawn.

1 range numeric, specifies the range of legend.

width numeric, the width of the legend, if scale = TRUE the width is proportional to

the x-limits of the plotting window.

height numeric, the height of the legend, if scale = TRUE the height is proportional to

the y-limits of the plotting window.

scale logical, if set to TRUE, the width and height of the legend will be calculated

proportional to the x- and y-limits of the plotting window.

xlim numeric, the x-limits of the plotting window the legend should be added for,

numeric vector, e.g., returned from function range.

ylim numeric, the y-limits of the plotting window the legend should be added for,

numeric vector, e.g., returned from function range.

plot logical, if set to TRUE, the legend will be drawn in a separate plotting window.

full logical, if set to TRUE, the legend will be drawn using the full window range.

add logical, if set to TRUE, the legend will be added to an existing plot.

col.border the color of the surrounding border line of the legend.

lty.border the line type of the surrounding border line of the legend.

lwd.border the line width of the surrounding border line of the legend.

ticks logical, if set to TRUE, ticks will be added to the legend.

at numeric, specifies at which locations ticks and labels should be added.

col.ticks the colors of the ticks.
lwd.ticks the line width of the ticks.
lty.ticks the line type of the ticks.

length.ticks	numeric, the length of the ticks as percentage of the height or width of the colorlegend.
labels	character, specifies labels that should be added to the ticks.
distance.labels	3
	numeric, the distance of the labels to the ticks, proportional to the length of the ticks.
col.labels	the colors of the labels.
cex.labels	text size of the labels.
digits	integer, the decimal places if labels are numerical.
swap	logical, if set to TRUE colors will be represented in reverse order.
symmetric	logical, if set to TRUE, a symmetric legend will be drawn corresponding to the +- max(abs(x)) value.
xpd	sets the xpd parameter in function par.
title	character, a title for the legend.
side.title	integer, 1 or 2. Specifies where the legend is placed, either on top if side.title = 1 or at the bottom if side.title = $2$ .
shift.title	numeric vector of length 2. Specifies a possible shift of the title in either x- or y-direction.
	other graphical parameters to be passed to function text.

# Value

A named list with the colors generated, the breaks and the function map, which may be used for mapping of x values to the colors specified in argument colors, please see the examples below.

# Author(s)

Nikolaus Umlauf, Thomas Kneib, Stefan Lang, Achim Zeileis.

# **Examples**

```
## play with colorlegend
colorlegend()
colorlegend(side.legend = 2)
colorlegend(side.legend = 2, side.ticks = 2)
colorlegend(height = 2)
colorlegend(width = 1, height = 0.8, scale = FALSE,
    pos = c(0, 0.2), length.ticks = 0.5)
colorlegend(color = heat.colors, ncol = 9)
colorlegend(color = heat.colors, ncol = 9, swap = TRUE)
colorlegend(pos = "bottomleft")
colorlegend(pos = "topleft")
colorlegend(pos = "topright")
colorlegend(pos = "bottomright")

## take x values for the color legend
```

```
x < -runif(100, -2, 2)
colorlegend(color = diverge\_hcl, x = x)
colorlegend(color = diverge_hcl, x = x, at = c(-1.5, 0, 1.5))
colorlegend(color = diverge_hcl, x = x, at = c(-1.5, 0, 1.5),
 labels = c("low", "middle", "high"))
colorlegend(color = rainbow_hcl, x = x, at = c(-1.5, 0, 1.5),
 labels = c("low", "middle", "high"), length.ticks = 1.5)
colorlegend(color = heat_hcl, x = x, at = c(-1.5, 0, 1.5),
 labels = c("low", "middle", "high"), length.ticks = 1.5,

cprob

**Extract Contour Probabilities** 

# Description

Function to extract estimated contour probabilities of a particular effect estimated with P-splines using Markov chain Monte Carlo (MCMC) estimation techniques. Note that, the contour probability option must be specified within function sx, see the example.

# Usage

```
cprob(object, model = NULL, term = NULL, ...)
```

#### **Arguments**

object	an object of class "bayesx".
model	for which model the contour probabilities should be provided, either an integer or a character, e.g. model = "mcmc.model".
term	if not NULL, the function will search for the term contour probabilities should be extracted for, either an integer or a character, eg term = $"s(x)"$ .
	not used.

# Author(s)

delete.neighbor

Delete Neighborhood Relations

# **Description**

Adds the neighborhhod relationship between two given regions from a map object in graph format.

# Usage

```
delete.neighbor(map, region1, region2)
```

# **Arguments**

```
map map object in graph format that should be modified. region1, region2
```

names of the regions that should no longer be regarded as neighbors.

# Value

Returns an adjacency matrix that represents the neighborhood structure of map minus the deleted neighborhood relation in graph format.

#### Author(s)

Felix Heinzl, Thomas Kneib.

fitted.bayesx 35

fi	tt	ed	. bav	/esx

Extract BayesX Fitted Values and Residuals

#### **Description**

Extractor functions to the fitted values/model residuals of the estimated model with bayesx and fitted model term partial effects/residuals.

# Usage

```
## S3 method for class 'bayesx'
fitted(object, model = NULL, term = NULL, ...)
## S3 method for class 'bayesx'
residuals(object, model = NULL, term = NULL, ...)
```

# **Arguments**

object	an object of class "bayesx".
mode1	for which model the fitted values/residuals should be provided, either an integer or a character, e.g. model = "mcmc.model".
term	if not NULL, the function will search for the term fitted values/residuals specified here, either an integer or a character, eg term = $"sx(x)"$ .
	not used.

#### Value

For fitted.bayesx, either the fitted linear predictor and mean or if e.g. term = "sx(x)", an object with class "xx.bayesx", where "xx" is depending of the type of the term. In principle the returned term object is simply a data.frame containing the covariate(s) and its effects, depending on the estimation method, e.g. for MCMC estimated models, mean/median fitted values and other quantities are returned. Several additional informations on the term are provided in the attributes of the object. For all types of terms plotting functions are provided, see function plot.bayesx.

Using residuals.bayesx will either return the mean model residuals or the mean partial residuals of a term specified in argument term.

ForestHealth

Forest Health Data

## **Description**

The data set consists of 16 variables with 1796 observations on forest health to identify potential factors influencing the health status of trees and therefore the vital status of the forest. In addition to covariates characterizing a tree and its stand, the exact locations of the trees are known. The interest is on detecting temporal and spatial trends while accounting for further covariate effects in a flexible manner.

## Usage

```
data("ForestHealth")
```

### **Format**

A data frame containing 1793 observations on 16 variables.

id: tree location identification number.

year: year of census.

**defoliation:** percentage of tree defoliation in three ordinal categories, 'defoliation < 12.5%', '12.5%' <= defoliation < 50%' and 'defoliation >= 50%'

x: x-coordinate of the tree location.

y: y-coordinate of the tree location.

age: age of stands in years.

**canopy:** forest canopy density in percent. **inclination:** slope inclination in percent.

38 ForestHealth

```
elevation: elevation (meters above sea level).
```

soil: soil layer depth in cm.ph: soil pH at 0-2cm depth.

**moisture:** soil moisture level with categories 'moderately dry', 'moderately moist' and 'moist or temporarily wet'.

alkali: proportion of base alkali-ions with categories 'very low', 'low', 'high' and 'very high'.

humus: humus layer thickness in cm, categorical coded.

stand: stand type with categories 'deciduous' and 'mixed'.

fertilized: fertilization applied with categories 'yes' and 'no'.

GAMart 39

GAMart

GAM Artificial Data Set

## **Description**

This is an artificial data set mainly used to test the **R2BayesX** interfacing functions. The data includes three different types of response variables. One numeric, one binomial and a categorical response with 4 different levels. In addition, several numeric and factor covariates are provided. The data set is constructed such that the observations are based upon different locations (pixels in 'longitude' and 'latitude' coordinates) obtained from a regular grid.

## Usage

```
data("GAMart")
```

#### **Format**

A data frame containing 500 observations on 12 variables.

num: numeric, response variable.

bin: factor, binomial response variable with levels "no" and "yes".

cat: factor, multi categorical response with levels "none", "low", "medium" and "high".

x1: numeric covariate.

x2: numeric covariate.

x3: numeric covariate.

fac: factor covariate with levels "low", "medium" and "high".

id: factor, pixel identification index.

long: numeric, the longitude coordinate of the pixel.

lat: numeric, the latitude coordinate of the pixel.

44 GRstats

GRstats	Compute Gelman and Rubin's convergence diagnostics from multicore
	BayesX models.

### **Description**

This function takes a fitted bayesx object estimated with multiple chains/cores and computes the Gelman and Rubin's convergence diagnostic of the model parameters using function gelman.diag provided in package coda.

### Usage

```
GRstats(object, term = NULL, ...)
```

## **Arguments**

object an object of class "bayesx", returned from the model fitting function bayesx using the multiple chain or core option.

term character or integer. The term for which the diagnostics should be computed, see also function samples.

... arguments passed to function gelman.diag.

## Value

An object returned from gelman.diag.

## Author(s)

Nikolaus Umlauf, Thomas Kneib, Stefan Lang, Achim Zeileis.

#### See Also

Interface between nb and gra format

Convert nb and gra format into each other

# Description

Convert neighborhood structure objects of class "nb" from R-package **spdep** to graph objects of class "gra" from R-package **R2BayesX** and vice versa.

### Usage

```
nb2gra(nb0bject)
gra2nb(gra0bject)
```

## Arguments

nbObject neighborhood structure object of class "nb" graObject graph object of class "gra"

#### Value

Equivalent object in the other format.

### Author(s)

Daniel Sabanes Bove.

# See Also

sp2bnd, bnd2sp for conversion between the geographical information formats and read.gra, write.gra for the interface to the **R2BayesX** files.

## **Examples**

```
## first nb to gra:
if(requireNamespace("spdep") &
 requireNamespace("rgdal") &
 requireNamespace("spData")) {
 library("spdep")
 library("spData")
 library("rgdal")
 columbus <- readOGR(system.file("shapes/columbus.shp", package="spData")[1])</pre>
 colNb <- poly2nb(columbus)</pre>
 ## ... here manual editing is possible ...
 ## then export to graph format
 colGra <- nb2gra(colNb)</pre>
 ## and save in BayesX file
 graFile <- tempfile()</pre>
 write.gra(colGra, file=graFile)
 ## now back from gra to nb:
 colGra <- read.gra(graFile)</pre>
 newColNb <- gra2nb(colGra)</pre>
 newColNb
 ## compare this with the original
 colNb
 ## only the call attribute does not match (which is OK):
 all.equal(newColNb, colNb, check.attributes = FALSE)
 attr(newColNb, "call")
 attr(colNb, "call")
```

Interface between sp and bnd format

Convert sp and bnd format into each other

## **Description**

Convert geographical information objects of class "SpatialPolygons" (or specializations) from R-package **sp** to objects of class "bnd" from R-package **R2BayesX** and vice versa.

### Usage

```
{\tt sp2bnd(sp0bject, regionNames, height2width, epsilon)} \\ {\tt bnd2sp(bnd0bject)}
```

#### **Arguments**

spObject object of class "SpatialPolygons" (or specializations).

regionNames character vector of region names (parallel to the Polygons list in spObject), defaults to the IDs.

height2width ratio of total height to width, defaults to the bounding box values.

epsilon how much can two polygons differ (in maximum squared Euclidean distance) and still match each other?, defaults to machine precision.

bndObject object of class "bnd".

#### Value

Equivalent object in the other format.

#### Author(s)

Daniel Sabanes Bove.

#### See Also

nb2gra, gra2nb for conversion between the neighborhood structure formats and read.bnd, write.bnd for the interface to the **R2BayesX** files.

```
## bnd to sp:
file <- file.path(find.package("R2BayesX"), "examples", "Germany.bnd")</pre>
germany <- read.bnd(file)</pre>
spGermany <- bnd2sp(germany)</pre>
## plot the result together with the neighborhood graph
if(requireNamespace("spdep")) {
 library("spdep")
 plot(spGermany)
 nbGermany <- poly2nb(spGermany)</pre>
 plot(nbGermany, coords = coordinates(spGermany), add = TRUE)

```

### **Examples**

```
## load MunichBnd and plot it
data("MunichBnd")
plotmap(MunichBnd)
```

parse.bayesx.input

Parse BayesX Input

### **Description**

Funtion to parse bayesx input parameters which are then send to write.bayesx.input.

# Usage

```
parse.bayesx.input(formula, data, weights = NULL,
   subset = NULL, offset = NULL, na.action = na.fail,
   contrasts = NULL, control = bayesx.control(...), ...)
```

# Arguments

formula	symbolic description of the model (of type y $\sim$ x). For more details see bayesx and sx.
data	a data. frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from environment(formula): typically the environment from which bayesx is called. Argument data may also be a character string defining the directory the data is stored, where the first row in the data set must contain the variable names and columns should be tab separated.
weights	prior weights on the data.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
offset	can be used to supply a model offset for use in fitting.
na.action	a function which indicates what should happen when the data contain NA's.
contrasts	an optional list. See the contrasts.arg of model.matrix.default.
control	specify several global control parameters for bayesx, see bayesx.control.
	arguments passed to bayesx.control.

### Value

Returns a list of class "bayesx.input" which is send to write.bayesx.input for processing within bayesx.

# Author(s)

Nikolaus Umlauf, Thomas Kneib, Stefan Lang, Achim Zeileis.

# **Examples**

```
parse.bayesx.input(y \sim x1 + sx(x2), data = "")
```

plot.bayesx	Default BayesX Plotting	
-------------	-------------------------	--

## **Description**

Generic functions for plotting objects of class "bayesx" and model term classes "geo.bayesx", "linear.bayesx", "mrf.bayesx", "random.bayesx" and "sm.bayesx".

# Usage

```
## S3 method for class 'bayesx'
plot(x, model = NULL, term = NULL, which = 1L, ask = FALSE, ...)
```

## **Arguments**

X	a fitted bayesx object.
model	for which model the plot should be provided, either an integer or a character, e.g. model = "mcmc.model".
term	the term that should be plotted, either an integer or a character, e.g. $term = "sx(x)"$ .
which	choose the type of plot that should be drawn, possible options are: "effect", "coef-samples", "var-samples", "intcpt-samples", "hist-resid", "qq-resid", "scatter-resid", "scale-resid", "max-acf". Argument which may also be specified as integer, e.g. which = 1. The first three arguments are all model term specific. For the residual model diagnostic plot options which may be set with which = 5:8.
ask	
• • •	other graphical parameters passed to plotblock, plotmap, plot2d, plot3d, acf and density.

### **Details**

Depending on the class of the term that should be plotted, function plot.bayesx calls one of the following plotting functions in the end:

- plotblock,
- plotsamples,
- plotmap,
- plot2d,
- plot3d,
- acf,
- density,

For details on argument specifications, please see the help sites for the corresponding function.

If argument x contains of more than one model and e.g. term = 2, the second terms of all models will be plotted

#### Note

If a model is specified with a structured and an unstructured spatial effect, e.g. the model formula is something like  $y \sim sx(id, bs = "mrf", map = MapBnd) + sx(id, bs = "re")$ , the model output contains of one additional total spatial effect, named with "sx(id):total". Also see the last example.

plot2d

2D Effect Plot

## Description

Function to plot simple 2D graphics for univariate effects/functions, typically used for objects of class "linear.bayesx" and "sm.bayesx" returned from function bayesx and read.bayesx.output.

### Usage

```
plot2d(x, residuals = FALSE, rug = TRUE, jitter = TRUE,
  col.residuals = NULL, col.lines = NULL, col.polygons = NULL,
  col.rug = NULL, c.select = NULL, fill.select = NULL,
```

54 plot2d

```
data = NULL, sep = "", month = NULL, year = NULL,
step = 12, shift = NULL, trans = NULL, ...)
```

## **Arguments**

Х

a matrix or data frame, containing the covariate for which the effect should be plotted in the first column and at least a second column containing the effect, typically the structure for univariate functions returned within bayesx and read.bayesx.output model term objects is used, also see fitted.bayesx. Another possibility is to specify the plot via a formula, e.g.  $y \sim x$ , also see the example. x may also be a character file path to the data to be used for plotting.

residuals if set to TRUE, partial residuals may also be plotted if available.

rug add a rug to the plot.

jitter if set to TRUE a jittered rug plot is added.

col.residuals the color of the partial residuals.

col.lines the color of the lines.

col. polygons specify the background color of polygons, if x has at least 3 columns, i.e. column

2 and 3 can form one polygon.

col.rug specify the color of the rug representation.

c. select integer vector of maximum length of columns of x, selects the columns of the

resulting data matrix that should be used for plotting. E.g. if x has 5 columns, then c.select = c(1, 2, 5) will select column 1, 2 and 5 for plotting. Note that first element of c.select should always be the column that holds the

variable for the x-axis.

fill.select

integer vector, select pairwise the columns of the resulting data matrix that should form one polygon with a certain background color specified in argument col. E.g. x has three columns, or is specified with formula  $f1 + f2 \sim x$ , then setting fill.select = c(0, 1, 1) will draw a polygon with f1 and f2 as boundaries. If x has five columns or the formula is e.g.  $f1 + f2 + f3 + f4 \sim x$ , then setting fill.select = c(0, 1, 1, 2, 2), the pairs f1, f2 and f3, f4 are selected to form two polygons.

data if x is a formula, a data. frame or list. By default the variables are taken from

 ${\tt environment(x): typically the environment from which plot2d is called. \ Note}$ 

that data may also be a character file path to the data.

sep the field separator character when x or data is a character, see function read.table.

month, year, step

provide specific annotation for plotting estimation results for temporal variables. month and year define the minimum time point whereas step specifies the type of temporal data with step = 4, step = 2 and step = 1 corresponding to

quartely, half yearly and yearly data.

shift numeric. Constant to be added to the smooth before plotting.

trans function to be applied to the smooth before plotting, e.g., to transform the plot

to the response scale.

... other graphical parameters, please see the details.

plot2d 55

### **Details**

For 2D plots the following graphical parameters may be specified additionally:

- cex: specify the size of partial residuals,
- 1ty: the line type for each column that is plotted, e.g. 1 ty = c(1, 2),
- lwd: the line width for each column that is plotted, e.g. lwd = c(1, 2),
- poly.lty: the line type to be used for the polygons,
- poly. lwd: the line width to be used for the polygons,
- density angle, border: see polygon,
- ...: other graphical parameters, see function plot.

```

plot3d

3D Effect Plot

### **Description**

Function to plot 3D graphics or image and/or contour plots for bivariate effects/functions, typically used for objects of class "sm.bayesx" and "geo.bayesx" returned from function bayesx and read.bayesx.output.

#### Usage

```
plot3d(x, residuals = FALSE, col.surface = NULL,
  ncol = 99L, swap = FALSE, col.residuals = NULL, col.contour = NULL,
  c.select = NULL, grid = 30L, image = FALSE, contour = FALSE,
  legend = TRUE, cex.legend = 1, breaks = NULL, range = NULL,
  digits = 2L, d.persp = 1L, r.persp = sqrt(3), outscale = 0,
  data = NULL, sep = "", shift = NULL, trans = NULL,
  type = "akima", linear = FALSE, extrap = FALSE,
  k = 40, ...)
```

### Arguments

Х

a matrix or data frame, containing the covariates for which the effect should be plotted in the first and second column and at least a third column containing the effect, typically the structure for bivariate functions returned within bayesx and read.bayesx.output model term objects is used, also see fitted.bayesx. Another possibility is to specify the plot via a formula, e.g. for simple plotting of bivariate surfaces  $z \sim x + y$ , also see the example. x may also be a character file path to the data to be used for plotting.

residuals if set to TRUE, partial residuals may also be plotted if available.

col.surface the color of the surface, may also be a function, e.g. col.surface = heat.colors.

ncol the number of different colors that should be generated, if col.surface is a

function.

swap if set to TRUE colors will be represented in reverse order.

col.residuals the color of the partial residuals, or if contour = TRUE the color of the contour

lines.

col. contour the color of the contour lines.

c. select integer vector of maximum length of columns of x, selects the columns of the

resulting data matrix that should be used for plotting. E.g. if x has 5 columns, then c.select = c(1, 2, 5) will select column 1, 2 and 5 for plotting. If c.select = 95 or c.select = 80, function plot3d will search for the corresponding columns to plot a 95% or 80% confidence surfaces respectively. Note that if e.g. c.select = c(1, 2), plot3d will use columns 1 + 2 and 2 + 3

2 for plotting.

grid the grid size of the surface(s).

image if set to TRUE, an image.plot is drawn. contour if set to TRUE, a contour plot is drawn.

legend if image = TRUE an additional legend may be added to the plot.

cex.legend the expansion factor for the legend text, see text.

breaks a set of breakpoints for the colors: must give one more breakpoint than ncol.

range specifies a certain range values should be plotted for.

digits specifies the legend decimal places.
d.persp see argument d in function persp.
r.persp see argument r in function persp.

outscale scales the outer ranges of x and z limits used for interpolation.

data if x is a formula, a data.frame or list. By default the variables are taken

from environment(x): typically the environment from which plot3d is called.

Note that data may also be a character file path to the data.

sep the field separator character when x or data is a character, see function read.table.

shift numeric. Constant to be added to the smooth before plotting.

trans function to be applied to the smooth before plotting, e.g., to transform the plot

to the response scale.

type character. Which type of interpolation metjod should be used. The default is

type = "akima", see function interp. The two other options are type = "mba", which calls function mba. surf of package MBA, or type = "mgcv", which uses a spatial smoother withing package mgcv for interpolation. The last option is definitely the slowest, since a full regression model needs to be estimated.

linear logical. Should linear interpolation be used withing function interp?

extrap logical. Should interpolations be computed outside the observation area (i.e.,

extrapolated)?

k integer. The number of basis functions to be used to compute the interpolated surface when type = "mgcv".
... parameters passed to colorlegend if an image plot with legend is drawn, also other graphical parameters, please see the details.

#### **Details**

For 3D plots the following graphical parameters may be specified additionally:

- cex: specify the size of partial residuals,
- col: it is possible to specify the color for the surfaces if se > 0, then e.g. col = c("green", "black", "red"),
- pch: the plotting character of the partial residuals,
- ...: other graphical parameters passed functions persp, image.plot and contour.

#### Note

Function plot3d uses per default the **akima** package to construct smooth interpolated surfaces, therefore, package **akima** needs to be installed. The **akima** package has an ACM license that restricts applications to non-commercial usage, see

```
http://www.acm.org/publications/policies/softwarecrnotice
```

Function plot3d prints a note referring to the ACM licence. This note can be supressed by setting options("use.akima" = TRUE)

```

plotblock

Factor Variable and Random Effects Plots

## **Description**

Function to plot effects for model terms including factor, or group variables for random effects, typically used for objects created within bayesx or read.bayesx.output.

## Usage

```
plotblock(x, residuals = FALSE, range = c(0.3, 0.3),
  col.residuals = "black", col.lines = "black", c.select = NULL,
  fill.select = NULL , col.polygons = NULL, data = NULL,
  shift = NULL, trans = NULL, ...)
```

#### **Arguments**

Χ

either a list of length of the unique factors, where each list element contains the estimated effects for one factor as a matrix, see fitted.bayesx, or one data matrix with first column as the group or factor variable. Also formulas are accepted, e.g it is possible to specify the plot with  $f \sim x$  or  $f1 + f2 \sim x$ . By convention, the covariate for which effects should be plotted, is always in the first column in the resulting data matrix, that is used for plotting, i.e. in the second formula example, the data matrix is cbind(x, f1, f2), also see argument c.select and fill.select.

residuals

if set to TRUE, partial residuals will be plotted if available. Partial residuals may be set as an attribute of x named "partial.resids", where the partial residuals must be a matrix with first column specifying the covariate, and second column the partial residuals that should be plotted.

range

numeric vector, specifying the left and right bound of the block.

col.residuals

the color of the partial residuals.

col.lines

vector of maximum length of columns of x minus 1, specifying the color of the lines.

c.select

integer vector of maximum length of columns of x, selects the columns of the resulting data matrix that should be used for plotting. E.g. if x has 5 columns, then c.select = c(1, 2, 5) will select column 1, 2 and 5 for plotting. Note that first element of c.select should always be 1, since this is the column of the covariate the effect is plotted for.

plotblock 61

fill.	select	integer vector, select pairwise the columns of the resulting data matrix that should form one polygon with a certain background color specified in argument col. E.g. x has three columns, or is specified with formula $f1 + f2 \sim x$ , then setting fill.select = $c(0, 1, 1)$ will draw a polygon with f1 and f2 as boundaries. If x has five columns or the formula is e.g. $f1 + f2 + f3 + f4 \sim x$ , then setting fill.select = $c(0, 1, 1, 2, 2)$ , the pairs f1, f2 and f3, f4 are selected to form two polygons.
col.p	olygons	specify the background color for the upper and lower confidence bands, e.g. $col = c("green", "red")$ .
data		if x is a formula, a data.frame or list. By default the variables are taken from environment(x): typically the environment from which plotblock is called.
shift		numeric. Constant to be added to the smooth before plotting.
trans		function to be applied to the smooth before plotting, e.g., to transform the plot to the response scale.
		graphical parameters, please see the details.

### **Details**

Function plotblock draws for every factor or group the effect as a "block" in one graphic, i.e. similar to boxplots, estimated fitted effects, e.g. containing quantiles for MCMC estimated models, are drawn as one block, where the upper lines represent upper quantiles, the middle line the mean or median, and lower lines lower quantiles, also see the examples. The following graphical parameters may be supplied additionally:

- cex: specify the size of partial residuals,
- 1ty: the line type for each column that is plotted, e.g. 1 ty = c(1, 2),
- lwd: the line width for each column that is plotted, e.g. lwd = c(1, 2),
- poly.lty: the line type to be used for the polygons,
- poly.lwd: the line width to be used for the polygons,
- density angle, border: see polygon,
- ...: other graphical parameters, see function plot.

  fill.select = c(0, 1, 1), poly.lty = 2, lty = 1,
  border = "grey5")
```

plotmap

Plot Maps

## Description

The function takes a list polygons and draws the corresponding map. Different colors for each polygon can be used. Typically used for objects of class "mrf.bayesx" and "random.bayesx" returned from function bayesx and read.bayesx.output.

### Usage

```
plotmap(map, x = NULL, id = NULL, c.select = NULL, legend = TRUE,
   missing = TRUE, swap = FALSE, range = NULL, names = FALSE,
   values = FALSE, col = NULL, ncol = 100, breaks = NULL,
   cex.legend = 1, cex.names = 1, cex.values = cex.names, digits = 2L,
   mar.min = 2, add = FALSE, interp = FALSE, grid = 200,
   land.only = FALSE, extrap = FALSE, outside = FALSE, type = "akima",
   linear = FALSE, k = 40, p.pch = 15, p.cex = 1, shift = NULL,
   trans = NULL, ...)
```

#### **Arguments**

map	the map to be plotted, the map object must be a list of matrices with first column indicating the x coordinate and second column the y coordinate each, also see polygon.
x	a matrix or data frame with two columns, first column indicates the region and second column the the values which will define the background colors of the polygons, e.g. fitted values from bayesx. More columns are possible, e.g. quantiles, which can accessed with argument se.
id	if argument x is a vector, argument id should contain a character vector of the same length of x with entries indicating the polygon the $i$ -th value of x belongs to, i.e. id must contain the same names as polygon names in map.
c.select	select the column of the data in $x$ which should be used for plotting, may be an integer or character with the corresponding column name.
legend	if set to TRUE, a legend will be shown.
missing	should polygons be plotted for which no data is available in x?
swap	if set to TRUE, colors will be represented in reverse order.

specify the range of values in x which should enter the plot, e.g. only values range between -2 and 2 are of interest then range = c(-2, 2). if set to TRUE the name for each polygon will also be plotted at the centroids of names the corresponding polygons. values if set to TRUE the corresponding values for each polygon will also be plotted at the centroids of the polygons. col the color of the surface, may also be a function, e.g. col.surface = heat.colors. ncol the number of different colors that should be generated if col is a function. breaks a set of breakpoints for the colors: must give one more breakpoint than ncol. cex.legend text size of the numbers in the legend. text size of the names if names = TRUE. cex.names cex.values text size of the names if values = TRUE. digits specifies the legend decimal places. Controls the definition of boundaries. Could be either NULL for individual setmar.min tings of mar or a value which defines mar as follows: The boundaries will be calculated according to the height to width ratio of the map with minimal boundary mar.min. add if set to TRUE, the map will be added to an existing plot. interp logical. Should the values provided in argument x be interpolated to obtain a smooth colored map. grid integer. Defines the number of grid cells to be used for interpolation. land.only if set to TRUE, only interpoltated pixels that cover land are drawn, see also function map. where. extrap logical. Should interpolations be computed outside the observation area (i.e., extrapolated)? outside logical. Should interpolated values outside the boundaries of the map be plotted. character. Which type of interpolation metjod should be used. The default is type type = "akima", see function interp. The two other options are type = "mba", which calls function mba. surf of package MBA, or type = "mgcv", which uses a spatial smoother withing package mgcv for interpolation. The last option is definitely the slowest, since a full regression model needs to be estimated. linear logical. Should linear interpolation be used withing function interp? integer. The number of basis functions to be used to compute the interpolated surface when type = "mgcv". p.pch numeric. The point size of the grid cells when using interpolation. numeric. The size of the grid cell points whein using interpolation. p.cex shift numeric. Constant to be added to the smooth before plotting. trans function to be applied to the smooth before plotting, e.g., to transform the plot to the response scale. parameters to be passed to colorlegend and others, e.g. change the border of

the polygons and density, see polygon. Please see the exmaples.

#### Note

Function plotmap uses per default the **akima** package to construct smooth interpolated surfaces, therefore, package **akima** needs to be installed. The **akima** package has an ACM license that restricts applications to non-commercial usage, see

```
http://www.acm.org/publications/policies/softwarecrnotice
```

Function plotmap prints a note referring to the ACM licence. This note can be supressed by setting options("use.akima" = TRUE)

68 plotsamples

## **Description**

This function plots the sampling paths of coefficient(s) and variance(s) stored in model term objects typically returned from function bayesx or read.bayesx.output.

## Usage

```
plotsamples(x, selected = "NA", acf = FALSE, var = FALSE,
  max.acf = FALSE, subset = NULL, ...)
```

## **Arguments**

х	a vector or matrix, where each column represents a different sampling path to be plotted.
selected	a character string containing the term name the sampling paths are plotted for.
acf	if set to TRUE, the autocorrelation function for each sampling path is plotted.
var	indicates whether coefficient or variance sampling paths are displayed and simply changes the main title.
max.acf	if set to TRUE, plotsamples will evaluate the maximum autocorrelation over all parameters of each sample.
subset	integer. An index which selects the coefficients for which sampling paths should be plotted.
	other graphical parameters to be passed to plot and acf, e.g. argument lag.max if acf = TRUE. An argument ask controls the display when more than 12 sampling paths should be plotted.

predict.bayesx

Prediction from fitted BayesX objects

### **Description**

Takes a fitted "bayesx" object returned from bayesx and produces predictions by refitting the initial model with weights set to zero for new observations.

## Usage

```
## S3 method for class 'bayesx'
predict(object, newdata, model = NULL,
   type = c("response", "link", "terms", "model"),
   na.action = na.pass, digits = 5, ...)
```

### **Arguments**

object an object of class "bayesx" or "bayesx.hpc".

newdata a data frame or list containing the values of the model covariates at which pre-

dictions are required. If missing newdata is the model.frame of the provided

model.

70 predict.bayesx

model for which model should predictions be calculated, either an integer or a charac-

ter, e.g. model = "mcmc.model". Note that exactly one model must be selected

within argument model to compute predicted values!

type when type = "response", the default, predictions on the scale of the response

are returned, "link" returns the linear predictor. When type = "terms", each component of the linear predictor is returned, but excludes any offset and intercept. If type = "model", the full model returned from updating the initial

model with weights, that is used for computing predictions, is returned.

na.action function determining what should be done with missing values in newdata.

digits predictions should usually be based on the new values provided in argument

newdata. However, since this prediction method uses refitting of the model with weights, predictions for model terms need to be matched with the new observations. **BayesX** returns values with a lower precision than R, therefore argument digits is used to round values when type = "terms", to find matching newdata pairs in the fitted objects returned from the refitted model and the new data. Note that this is a workaround and not 100% bulletproof. It is recommended to compute predictions for type = "response" or type = "link".

... not used.

#### Value

Depending on the specifications of argument type.

#### Note

This prediction method is based on refitting the initial model with weights, i.e., if new observations lie outside the domain of the respective covariate, the knot locations when using e.g. P-splines are calculated using the old and the new data. Hence, if there are large gaps between the old data domain and new observations, this could affect the overall fit of the estimated spline, i.e., compared to the initial model fit there will be smaller or larger differences depending on the newdata provided.

read.bayesx.output

Read BayesX Output from Directories

### **Description**

This function automatically reads in **BayesX** estimation output which is stored in an output directory.

## Usage

```
read.bayesx.output(dir, model.name = NULL)
```

### **Arguments**

dir

a character string, specifies the directory file where **BayesX** output is stored.

model.name

a character string, specifies the base name of the model that should be read in, also see the examples. If not supplied read.bayesx.output tries to read in all existing model outputs in dir, every model is then stored as one element in the output list. By convention, read.bayesx.output searches for existing .tex output files, and others, to identify different models in the dir folder.

## **Details**

The function searches for model term objects in the specified directory, which are then stored in a list. Each model term object will be of class xx.bayesx, so the generic functions described in plot.bayesx may be applied for visualizing the results. In addition summary statistics of the models may be printed to the R console with summary.bayesx.

72 read.bayesx.output

#### Value

read.bayesx.output typically returns a list of class "bayesx" with the first element containing a list with the following objects:

formula the STAR formula used,

bayesx.setup an object of class "bayesx.input", see parse.bayesx.input,

bayesx.prg a character containing the .prg file used for estimation with run.bayesx,

bayesx.run details on processing with run.bayesx,

call the original function call,

fitted.values the fitted values of the estimated model, residuals the residuals of the estimated model,

effects a list containing fitted effects of model terms, also see fitted.bayesx and

samples,

fixed.effects a matrix with estimation results for fixed effects,

variance estimation results for the variance parameter of the model,

smooth.hyp a matrix with estimation results smooth terms,

model.fit list containing additional information to be supplied to summary.bayesx.

#### Author(s)

Nikolaus Umlauf, Thomas Kneib, Stefan Lang, Achim Zeileis.

read.bnd

Read Geographical Information in Boundary Format

## **Description**

Reads the geographical information provided in a file in boundary format and stores it in a map object.

## Usage

```
read.bnd(file, sorted = FALSE)
```

## **Arguments**

file name of the boundary file to be read.

should the regions be ordered by the numbers speciying the region names (sorted = TRUE)?

## **Details**

A boundary file provides the boundary information of a geographical map in terms of closed polygons. For each region of the map, the boundary file contains a block of lines defining the name of the region, the number of lines the polygon consists of, and the polygons themselves. The first line of such a block contains the region code surrounded by quotation marks and the number of lines the polygon of the region consists of. The region code and the number of lines must be separated by a comma. The subsequent lines contain the coordinates of the straight lines that form the boundary of the region. The straight lines are represented by the coordinates of their end points. Coordinates must be separated by a comma.

The following is an example of a boundary file as provided in file Germany. bnd in the examples folder of this package.

"1001",9 2534.64771,8409.77539 2554.54712,8403.92285 2576.78735,8417.96973 2592.00439,8366.46582 2560.39966,8320.81445 2507.72534,8319.64453 2496.02002,8350.07813 2524.11304,8365.29492 74 read.gra

```
2534.64771,8409.77539
"1002",18
2987.64697,7774.17236
2954.87183,7789.38916
```

Hence, the region code of the first region is "1001" and contains of 9 points that form its polygon. The second region has region code "1002" and contains of 18 polygon points (note that only the first two points are shown).

#### Value

Returns a list of polygons that form the map. Additional attributes are

surrounding Parallel list where for each polygon, the name of a possible surrounding region

is saved.

height2width Ratio between height and width of the map. Allows customised drawing and

storage in files by specifying the appropriate height and width.

#### Author(s)

Daniel Sabanes Bove, Felix Heinzl, Thomas Kneib, Andreas Brezger.

```
file <- file.path(find.package("R2BayesX"), "examples", "Germany.bnd")
germany <- read.bnd(file)
plotmap(germany)</pre>
```

read.gra

Read Geographical Information in Graph Format

## **Description**

Reads the geographical information provided in a file in graph format and stores it in a map object.

## Usage

```
read.gra(file, sorted = FALSE, sep = " ")
```

read.gra 75

## **Arguments**

file	the file path of the graph file to be read.
sorted	logical. Should the regions be ordered by the numbers specifying the region names (sorted = TRUE)?
sep	the field separator character. Values on each line of the file are separated by this character.

#### **Details**

A graph file stores the nodes and the edges of a graph and is a convenient way to represent the neighborhood structure of a geographical map. The structure of a graph file is given by:

- The first line of the graph file specifies the total number of nodes.
- The subsequent three lines correspond to the node with the name given in line 2, the number of neighbors in line 3 and the neighboring node identity numbers in line 4.

Note that the note identity numbering starts with 0. Example taken from the package example file Germany.gra:

```
309

1001

1

1

1059

3

0 3 4

1002

2

5 4

1051

3

4 1 9

1058

7

2 6 3 5 1 10 9

...
```

Hence, this graph file contains of 309 regions. The first region with name 1001 has 1 neighbor with neighboring node identity number 1. The last region in this example, region 1058, has 7 neighbors with neighboring node identity numbers 2 6 3 5 1 10 9.

In addition, graph files using the following format may be imported:

- The first line of the graph file specifies the total number of nodes.
- The subsequent lines start with the node name followed by the number of neighbors and the neighboring node identity numbers.

Example:

76 samples

```
309

1001 1 2

1059 3 1 4 5

1002 2 6 5

1051 3 5 2 10

1058 7 3 7 4 6 2 11 10
```

## Value

Returns an adjacency matrix that represents the neighborhood structure defined in the graph file. The diagonal elements of this matrix are the number of neighbors of each region. The off-diagonal elements are either -1 if regions are neighbors else 0.

samples

Extract Samples of Coefficients and Variances

## **Description**

Function to extract the samples generated with Markov chain Monte Carlo simulation.

# Usage

```
samples(object, model = NULL, term = NULL, coda = TRUE, acf = FALSE, ...)
```

samples 77

# **Arguments**

object	an object of class "bayesx".
mode1	for which model the samples should be provided, either an integer or a character, e.g. model = "mcmc.model".
term	<pre>character or integer, the term for which samples should be extracted. Also samples of linear effects may be returned if available and term = "linear-samples", or of the variance if term = "var-samples". If set to NULL, the samples of the linear effects will be returned.</pre>
acf	if set to TRUE, the autocorrelation function of the samples will be provided.
coda	if set to TRUE the function will return objects of class "mcmc" or "mcmc.list" as provided in the <b>coda</b> package.
	further arguments passed to function acf, e.g. argument lag.max if acf = TRUE.

# Value

A data.frame or an object of class "mcmc" or "mcmc.list", if argument coda = TRUE.

shp2bnd

convert a shape-file into a boundary object

## **Description**

Converts the geographical information provided in a shape-file into a boundary object (see Chapter 5 of the **BayesX** Reference Manual)

## Usage

```
shp2bnd(shpname, regionnames, check.is.in = TRUE)
```

## **Arguments**

shpname base filename of the shape-file (including path)

regionnames either a vector of region names or the name of the variable in the dbf-file repre-

senting these names

check.is.in test whether some regions are surrounded by other regions (FALSE speeds up the

execution time but may result in a corrupted bnd-file)

## Value

Returns a boundary object, i.e. a list of polygons that form the map. See read.bnd for more information on the format.

sliceplot

Plot Slices of Bivariate Functions

#### **Description**

This function plots slices from user defined values of bivariate surfaces.

### Usage

```
sliceplot(x, y = NULL, z = NULL, view = 1, c.select = NULL,
values = NULL, probs = c(0.1, 0.5, 0.9), grid = 100,
legend = TRUE, pos = "topright", digits = 2, data = NULL,
rawdata = FALSE, type = "akima", linear = FALSE,
extrap = FALSE, k = 40, rug = TRUE, rug.col = NULL,
jitter = TRUE, ...)
```

## **Arguments**

X

a matrix or data frame, containing the covariates for which the effect should be plotted in the first and second column and at least a third column containing the effect, typically the structure for bivariate functions returned within bayesx and read.bayesx.output model term objects is used, also see fitted.bayesx. Another possibility is to specify the plot via a formula, e.g. for simple plotting of bivariate surfaces  $z \sim x + y$ , also see the example.

y if x is a vector the argument y and z must also be supplied as vectors.

80 sliceplot

Z	if x is a vector the argument y and z must also be supplied as vectors, z defines the surface given by $z=f(x,y).$
view	which variable should be used for the x-axis of the plot, the other variable will be used to compute the slices. May also be a character with the name of the corresponding variable.
c.select	integer, selects the column that is used in the resulting matrix to be used as the z argument.
values	the values of the x or y variable that should be used for computing the slices, if set to NULL, slices will be constructed according to the quantiles, see also argument probs.
probs	numeric vector of probabilities with values in [0,1] to be used within function quantile to compute the values for plotting the slices.
grid	the grid size of the surface where the slices are generated from.
legend	if set to TRUE, a legend with the values that where used for slicing will be added.
pos	the position of the legend, see also function legend.
digits	the decimal place the legend values should be rounded.
data	if x is a formula, a data.frame or list. By default the variables are taken from environment(x): typically the environment from which plot3d is called.
rawdata	if set to TRUE, the data will not be interpolated, only raw data will be used. This is useful when displaying data on a regular grid.
type	character. Which type of interpolation metjod should be used. The default is type = "akima", see function interp. The two other options are type = "mba", which calls function mba.surf of package MBA, or type = "mgcv", which uses a spatial smoother withing package mgcv for interpolation. The last option is definitely the slowest, since a full regression model needs to be estimated.
linear	logical. Should linear interpolation be used withing function interp?
extrap	logical. Should interpolations be computed outside the observation area (i.e., extrapolated)?
k	integer. The number of basis functions to be used to compute the interpolated surface when type = "mgcv".
rug	add a rug to the plot.
jitter	if set to TRUE a jittered rug plot is added.
rug.col	specify the color of the rug representation.
	parameters passed to matplot and legend.

# Details

Similar to function plot3d, this function first applies bivariate interpolation on a regular grid, afterwards the slices are computed from the resulting surface.

sliceplot 81

#### Note

Function sliceplot uses per default the **akima** package to construct smooth interpolated surfaces, therefore, package **akima** needs to be installed. The **akima** package has an ACM license that restricts applications to non-commercial usage, see

```
http://www.acm.org/publications/policies/softwarecrnotice
```

Function sliceplot prints a note referring to the ACM licence. This note can be supressed by setting

```
options("use.akima" = TRUE)
```

summary.bayesx

Bayesx Summary Statistics

## **Description**

Takes an object of class "bayesx" and displays summary statistics.

### Usage

```
## S3 method for class 'bayesx'
summary(object, model = NULL,
  digits = max(3, getOption("digits") - 3), ...)
```

## **Arguments**

object an object of class "bayesx".

model for which model the plot should be provided, either an integer or a character, e.g. model = "mcmc.model".

digits choose the decimal places of represented numbers in the summary statistics.

... not used.

# **Details**

This function supplies detailed summary statistics of estimated objects with **BayesX**, i.e. informations on smoothing parameters or variances are supplied, as well as random effects variances and parametric coefficients. Depending on the model estimated and the output provided, additional model specific information will be printed, e.g. if method = "MCMC" was specified in bayesx, the number of iterations, the burnin and so forth is shown. Also goodness of fit statistics are provided if the object contains such informations.

## End(Not run)
```

Construct BayesX Model Terms in A Formula

## **Description**

SX

Function sx is a model term constructor function for terms used within the formula argument of function bayesx. The function does not evaluate matrices etc., the behavior is similar to function s from package mgcv. It purely exists to build a basic setup for the model term which can be processed by function bayesx.construct.

## Usage

```
sx(x, z = NULL, bs = "ps", by = NA, ...)
```

## Arguments

by

x the covariate the model term is a function of.

z a second covariate.

bs a character string, specifying the basis/type which is used for this model term.

a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth, evaluated at the corresponding covariate values (a 'varying coefficient model' results). In the factor case the term is replicated for each factor level. Note that centering of the term may be needed, please see the notes.

... special controlling arguments or objects used for the model term, see also the examples and function bayesx.term.options for all possible optional parameters.

#### **Details**

The following term types may be specified using argument bs:

- "rw1", "rw2": Zero degree P-splines: Defines a zero degree P-spline with first or second order difference penalty. A zero degree P-spline typically estimates for every distinct covariate value in the dataset a separate parameter. Usually there is no reason to prefer zero degree P-splines over higher order P-splines. An exception are ordinal covariates or continuous covariates with only a small number of different values. For ordinal covariates higher order P-splines are not meaningful while zero degree P-splines might be an alternative to modeling nonlinear relationships via a dummy approach with completely unrestricted regression parameters.
- "season": Seasonal effect of a time scale.
- "ps", "psplinerw1", "psplinerw2": P-spline with first or second order difference penalty.
- "te", "pspline2dimrw1": Defines a two-dimensional P-spline based on the tensor product of one-dimensional P-splines with a two-dimensional first order random walk penalty for the parameters of the spline.
- "kr", "kriging": Kriging with stationary Gaussian random fields.
- "gk", "geokriging": Geokriging with stationary Gaussian random fields: Estimation is based on the centroids of a map object provided in boundary format (see function read.bnd and shp2bnd) as an additional argument named map within function sx, or supplied within argument xt when using function s, e.g., xt = list(map = MapBnd).
- "gs", "geospline": Geosplines based on two-dimensional P-splines with a two-dimensional first order random walk penalty for the parameters of the spline. Estimation is based on the coordinates of the centroids of the regions of a map object provided in boundary format (see function read.bnd and shp2bnd) as an additional argument named map (see above).
- "mrf", "spatial": Markov random fields: Defines a Markov random field prior for a spatial
  covariate, where geographical information is provided by a map object in boundary or graph
  file format (see function read.bnd, read.gra and shp2bnd), as an additional argument named
  map (see above).
- "b1", "baseline": Nonlinear baseline effect in hazard regression or multi-state models: Defines a P-spline with second order random walk penalty for the parameters of the spline for the log-baseline effect  $log(\lambda(time))$ .
- "factor": Special **BayesX** specifier for factors, especially meaningful if method = "STEP", since the factor term is then treated as a full term, which is either included or removed from the model.
- "ridge", "lasso", "nigmix": Shrinkage of fixed effects: defines a shrinkage-prior for the corresponding parameters  $\gamma_j$ ,  $j=1,\ldots,q,$   $q\geq 1$  of the linear effects  $x_1,\ldots,x_q$ . There are three priors possible: ridge-, lasso- and Normal Mixture of inverse Gamma prior.
- "re": Gaussian i.i.d. Random effects of a unit or cluster identification covariate.

#### Value

A list of class "xx.smooth.spec", where "xx" is a basis/type identifying code given by the bs argument of f.

#### Note

Some care has to be taken with the identifiability of varying coefficients terms. The standard in **BayesX** is to center nonlinear main effects terms around zero whereas varying coefficient terms are not centered. This makes sense since main effects nonlinear terms are not identifiable and varying coefficients terms are usually identifiable. However, there are situations where a varying coefficients term is not identifiable. Then the term must be centered. Since centering is not automatically accomplished it has to be enforced by the user by adding option center = TRUE in function f. To give an example, the varying coefficient terms in  $\eta = \ldots + g_1(z_1)z + g_2(z_2)z + \gamma_0 + \gamma_1 z + \ldots$  are not identified, whereas in  $\eta = \ldots + g_1(z_1)z + \gamma_0 + \ldots$ , the varying coefficient term is identifiable. In the first case, centering is necessary, in the second case, it is not.

term.freqs

Extract model term selection frequencies.

## **Description**

This function takes a fitted bayesx object and returns selection frequency tables of model terms. These tables are only returned using the stepwise procedure in combination with the bootstrap confidence intervals, see function bayesx.control.

# Usage

```
term.freqs(object, model = NULL, term = NULL, ...)
```

#### **Arguments**

object an object of class "bayesx".

model for which model the tables should be provided, either an integer or a character, e.g. model = "mcmc.model".

term character or integer. The term for which the frequency table should be extracted.

not used.

write.bayesx.input

Write the BayesX Program

## **Description**

Function write.bayesx.input takes an object from parse.bayesx.input and translates the input to an executable program file which may be send to the **BayesX** binary.

#### Usage

```
write.bayesx.input(object)
```

#### **Arguments**

object

An object of class "bayesx.input", see parse.bayesx.input

## **Details**

This function translates the model specified in the formula within parse.bayesx.input or bayesx into a **BayesX** executable program file, secondly the function writes a data file into the specified directory chosen in bayesx.control, parse.bayesx.input or bayesx, where **BayesX** will find the necessary variables for estimation.

90 write.bnd

## Value

Function returns a list containing a character string with all commands used within the executable of **BayesX**, the program name, model name and the file directory where the program file is stored.

## Author(s)

Nikolaus Umlauf, Thomas Kneib, Stefan Lang, Achim Zeileis.

## **Examples**

```
## generate some data
set.seed(111)
n <- 500
## regressors
dat <- data.frame(x = runif(n, -3, 3), z = runif(n, -3, 3),
   w = runif(n, 0, 6), fac = factor(rep(1:10, n/10)))
## response

ZambiaNutrition 93

ZambiaNutrition

Determinants of Childhood Malnutrition in Zambia

# **Description**

The Demographic Health Surveys (DHS) of Zambia was conducted 1992. The survey is produced jointly by Macro International, a USAIDfunded firm specializing in demographic research, and the national statistical agency of the country.

Malnutrition among children is usually determined by assessing an anthropometric status of the children relative to a reference standard. In our example, malnutrition is measured by stunting or insufficient height for age, indicating chronic malnutrition. Stunting for a child i is determined using a Z-score defined as

$$stunting_i = \frac{AI_i - MAI}{\sigma}$$

where AI refers to the child's anthropometric indicator (height at a certain age in our example), while MAI and  $\sigma$  correspond to the median and the standard deviation in the reference population, respectively.

The main interest is on modeling the dependence of malnutrition on covariates including the age of the child, the body mass index of the child's mother, the district the child lives in and some further categorial covariates.

## Usage

data("ZambiaNutrition")

#### **Format**

A data frame containing 4847 observations on 8 variables.

**stunting:** standardised Z-score for stunting. **mbmi:** body mass index of the mother. **agechild:** age of the child in months.

district: district where the mother lives.

memployment: mother's employment status with categories 'working' and 'not working'.

**meducation:** mother's educational status with categories for complete primary but incomplete secondary 'no/incomplete', complete secondary or higher 'minimum primary' and no education or incomplete primary 'minimum secondary'.

urban: locality of the domicile with categories 'yes' and 'no'.

**gender:** gender of the child with categories 'male' and 'female'.
