

# Package ‘entropy’

February 19, 2015

**Version** 1.2.1

**Date** 2014-11-14

**Title** Estimation of Entropy, Mutual Information and Related Quantities

**Author** Jean Hausser and Korbinian Strimmer

**Maintainer** Korbinian Strimmer <[strimmerlab@gmail.com](mailto:strimmerlab@gmail.com)>

**Depends** R (>= 2.15.1)

**Suggests**

**Description** This package implements various estimators of entropy, such as the shrinkage estimator by Hausser and Strimmer, the maximum likelihood and the Millow-Madow estimator, various Bayesian estimators, and the Chao-Shen estimator. It also offers an R interface to the NSB estimator. Furthermore, it provides functions for estimating Kullback-Leibler divergence, chi-squared, mutual information, and chi-squared statistic of independence. In addition there are functions for discretizing continuous random variables.

**License** GPL (>= 3)

**URL** <http://strimmerlab.org/software/entropy/>

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2014-11-14 08:16:32

---

entropy-package	<i>The entropy Package</i>
-----------------	----------------------------

---

**Description**

This package implements various estimators of the Shannon entropy. Most estimators in this package can be applied in “small n, large p” situations, i.e. when there are many more bins than counts.

The main function of this package is [entropy](#), which provides a unified interface to various entropy estimators. Other functions included in this package are estimators of Kullback-Leibler divergence ([KL.plugin](#)) and of mutual information ([mi.plugin](#)).

If you use this package please cite: Jean Hausser and Korbinian Strimmer. 2009. Entropy inference and the James-Stein estimator, with application to nonlinear gene association networks. *J. Mach. Learn. Res.* **10**: 1469-1484. Available online from <http://jmlr.csail.mit.edu/papers/v10/hausser09a.html>.

This paper contains a detailed statistical comparison of the estimators available in this package. It also describes the shrinkage entropy estimator [entropy.shrink](#).

---

discretize	<i>Discretize Continuous Random Variables</i>
------------	---

---

**Description**

*discretize* puts observations from a continuous random variable into bins and returns the corresponding vector of counts.

*discretize2d* puts observations from a pair of continuous random variables into bins and returns the corresponding table of counts.

**Usage**

```
discretize( x, numBins, r=range(x) )
discretize2d( x1, x2, numBins1, numBins2, r1=range(x1), r2=range(x2) )
```

**Arguments**

x	vector of observations.
x1	vector of observations for the first random variable.
x2	vector of observations for the second random variable.
numBins	number of bins.
numBins1	number of bins for the first random variable.
numBins2	number of bins for the second random variable.
r	range of the random variable (default: observed range).
r1	range of the first random variable (default: observed range).
r2	range of the second random variable (default: observed range).

**Details**

The bins for a random variable all have the same width. It is determined by the length of the range divided by the number of bins.

**Value**

`discretize` returns a vector containing the counts for each bin.  
`discretize2d` returns a matrix containing the counts for each bin.

**Author(s)**

Korbinian Strimmer (<http://strimmerlab.org>).

**See Also**

[entropy](#).

**Examples**

```
# load entropy library
library("entropy")

#### 1D example ####

# sample from continuous uniform distribution
x1 = runif(10000)
hist(x1, xlim=c(0,1), freq=FALSE)

# discretize into 10 categories
y1 = discretize(x1, numBins=10, r=c(0,1))
```

```

y1

# compute entropy from counts
entropy(y1) # empirical estimate near theoretical maximum
log(10) # theoretical value for discrete uniform distribution with 10 bins

# sample from a non-uniform distribution
x2 = rbeta(10000, 750, 250)
hist(x2, xlim=c(0,1), freq=FALSE)

# discretize into 10 categories and estimate entropy
y2 = discretize(x2, numBins=10, r=c(0,1))
y2
entropy(y2) # almost zero

#### 2D example ####

# two independent random variables
x1 = runif(10000)
x2 = runif(10000)

y2d = discretize2d(x1, x2, numBins1=10, numBins2=10)
sum(y2d)

# joint entropy
H12 = entropy(y2d )
H12
log(100) # theoretical maximum for 10x10 table

# mutual information
mi.empirical(y2d) # approximately zero

# another way to compute mutual information

# compute marginal entropies
H1 = entropy(rowSums(y2d))
H2 = entropy(colSums(y2d))

H1+H2-H12 # mutual entropy

```

**Description**

`entropy` estimates the Shannon entropy  $H$  of the random variable  $Y$  from the corresponding observed counts  $y$ .

`freqs` estimates bin frequencies from the counts  $y$ .

**Usage**

```
entropy(y, lambda.freqs, method=c("ML", "MM", "Jeffreys", "Laplace", "SG",
  "minimax", "CS", "NSB", "shrink"), unit=c("log", "log2", "log10"), verbose=TRUE, ...)
freqs(y, lambda.freqs, method=c("ML", "MM", "Jeffreys", "Laplace", "SG",
  "minimax", "CS", "NSB", "shrink"), verbose=TRUE)
```

**Arguments**

<code>y</code>	vector of counts.
<code>method</code>	the method employed to estimate entropy (see Details).
<code>unit</code>	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set <code>unit="log2"</code> .
<code>lambda.freqs</code>	shrinkage intensity (for "shrink" option).
<code>verbose</code>	verbose option (for "shrink" option).
<code>...</code>	option passed on to <a href="#">entropy.NSB</a> .

**Details**

The `entropy` function allows to estimate entropy from observed counts by a variety of methods:

- `method="ML"`:maximum likelihood, see [entropy.empirical](#)
- `method="MM"`:bias-corrected maximum likelihood, see [entropy.MillerMadow](#)
- `method="Jeffreys"`:[entropy.Dirichlet](#) with  $a=1/2$
- `method="Laplace"`:[entropy.Dirichlet](#) with  $a=1$
- `method="SG"`:[entropy.Dirichlet](#) with  $a=a=1/\text{length}(y)$
- `method="minimax"`:[entropy.Dirichlet](#) with  $a=\sqrt{\sum(y)}/\text{length}(y)$
- `method="CS"`:see [entropy.ChaoShen](#)
- `method="NSB"`:see [entropy.NSB](#)
- `method="shrink"`:see [entropy.shrink](#)

The `freqs` function estimates the underlying bin frequencies. Note that estimated frequencies are not available for `method="MM"`, `method="CS"` and `method="NSB"`. In these instances a vector containing NAs is returned.

**Value**

`entropy` returns an estimate of the Shannon entropy.

`freqs` returns a vector with estimated bin frequencies (if available).

**Author(s)**

Korbinian Strimmer (<http://strimmerlab.org>).

**See Also**

[entropy-package](#), [discretize](#).

## Examples

```
# load entropy library
library("entropy")

# observed counts for each bin
y = c(4, 2, 3, 0, 2, 4, 0, 0, 2, 1, 1)

entropy(y, method="ML")
entropy(y, method="MM")
entropy(y, method="Jeffreys")
entropy(y, method="Laplace")
entropy(y, method="SG")
entropy(y, method="minimax")
entropy(y, method="CS")
#entropy(y, method="NSB")
entropy(y, method="shrink")
```

**entropy.ChaoShen**      *Chao-Shen Entropy Estimator*

## Description

`entropy.ChaoShen` estimates the Shannon entropy H of the random variable Y from the corresponding observed counts y using the method of Chao and Shen (2003).

## Usage

```
entropy.ChaoShen(y, unit=c("log", "log2", "log10"))
```

## Arguments

- |                   |  |
|-------------------|--|
| <code>y</code>    | vector of counts.  |
| <code>unit</code> | the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set <code>unit="log2"</code> . |

## Details

The Chao-Shen entropy estimator (2003) is a Horvitz-Thompson (1952) estimator applied to the problem of entropy estimation, with additional coverage correction as proposed by Good (1953).

Note that the Chao-Shen estimator is not a plug-in estimator, hence there are no explicit underlying bin frequencies.

## Value

`entropy.ChaoShen` returns an estimate of the Shannon entropy.

# compare to empirical estimate
entropy.empirical(y)
```

**entropy.Dirichlet**

*Dirichlet Prior Bayesian Estimators of Entropy, Mutual Information and Other Related Quantities*

**Description**

`freqs.Dirichlet` computes the Bayesian estimates of the bin frequencies using the Dirichlet-multinomial pseudocount model.

`entropy.Dirichlet` estimates the Shannon entropy H of the random variable Y from the corresponding observed counts y by plug-in of Bayesian estimates of the bin frequencies using the Dirichlet-multinomial pseudocount model.

`KL.Dirichlet` computes a Bayesian estimate of the Kullback-Leibler (KL) divergence from counts y1 and y2.

`chi2.Dirichlet` computes a Bayesian version of the chi-squared statistic from counts y1 and y2.

`mi.Dirichlet` computes a Bayesian estimate of mutual information of two random variables.

`chi2indep.Dirichlet` computes a Bayesian version of the chi-squared statistic of independence from a table of counts y2d.

## Usage

```
freqs.Dirichlet(y, a)
entropy.Dirichlet(y, a, unit=c("log", "log2", "log10"))
KL.Dirichlet(y1, y2, a1, a2, unit=c("log", "log2", "log10"))
chi2.Dirichlet(y1, y2, a1, a2, unit=c("log", "log2", "log10"))
mi.Dirichlet(y2d, a, unit=c("log", "log2", "log10"))
chi2indep.Dirichlet(y2d, a, unit=c("log", "log2", "log10"))
```

## Arguments

y	vector of counts.
y1	vector of counts.
y2	vector of counts.
y2d	matrix of counts.
a	pseudocount per bin.
a1	pseudocount per bin for first random variable.
a2	pseudocount per bin for second random variable.
unit	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set unit="log2".

## Details

The Dirichlet-multinomial pseudocount entropy estimator is a Bayesian plug-in estimator: in the definition of the Shannon entropy the bin probabilities are replaced by the respective Bayesian estimates of the frequencies, using a model with a Dirichlet prior and a multinomial likelihood.

The parameter a is a parameter of the Dirichlet prior, and in effect specifies the pseudocount per bin. Popular choices of a are:

- a=0:maximum likelihood estimator (see [entropy.empirical](#))
- a=1/2:Jeffreys' prior; Krchevsky-Trovimov (1991) entropy estimator
- a=1:Laplace's prior
- a=1/length(y):Schurmann-Grassberger (1996) entropy estimator
- a=sqrt(sum(y))/length(y):minimax prior

The pseudocount a can also be a vector so that for each bin an individual pseudocount is added.

## Value

`freqs.Dirichlet` returns the Bayesian estimates of the frequencies .  
`entropy.Dirichlet` returns the Bayesian estimate of the Shannon entropy.  
`KL.Dirichlet` returns the Bayesian estimate of the KL divergence.  
`chi2.Dirichlet` returns the Bayesian version of the chi-squared statistic.  
`mi.Dirichlet` returns the Bayesian estimate of the mutual information.  
`chi2indep.Dirichlet` returns the Bayesian version of the chi-squared statistic of independence.

**Examples**

```
# load entropy library
library("entropy")

# a single variable

# observed counts for each bin
y = c(4, 2, 3, 0, 2, 4, 0, 0, 2, 1, 1)

# Dirichlet estimate of frequencies with a=1/2
freqs.Dirichlet(y, a=1/2)

# Dirichlet estimate of entropy with a=0
entropy.Dirichlet(y, a=0)

# identical to empirical estimate
entropy.empirical(y)

# Dirichlet estimate with a=1/2 (Jeffreys' prior)
entropy.Dirichlet(y, a=1/2)

# Dirichlet estimate with a=1 (Laplace prior)
entropy.Dirichlet(y, a=1)

# Dirichlet estimate with a=1/length(y)
entropy.Dirichlet(y, a=1/length(y))

# Dirichlet estimate with a=sqrt(sum(y))/length(y)
entropy.Dirichlet(y, a=sqrt(sum(y))/length(y))

# example with two variables
```

```

# observed counts for two random variables
y1 = c(4, 2, 3, 1, 10, 4)
y2 = c(2, 3, 7, 1, 4, 3)

# Bayesian estimate of Kullback-Leibler divergence (a=1/6)
KL.Dirichlet(y1, y2, a1=1/6, a2=1/6)

# half of the corresponding chi-squared statistic
0.5*chi2.Dirichlet(y1, y2, a1=1/6, a2=1/6)

## joint distribution example

# contingency table with counts for two discrete variables
y2d = rbind( c(1,2,3), c(6,5,4) )

# Bayesian estimate of mutual information (a=1/6)
mi.Dirichlet(y2d, a=1/6)

# half of the Bayesian chi-squared statistic of independence
0.5*chi2indep.Dirichlet(y2d, a=1/6)

```

## Description

`freqs.empirical` computes the empirical frequencies from counts  $y$ .

`entropy.empirical` estimates the Shannon entropy  $H$  of the random variable  $Y$  from the corresponding observed counts  $y$  by plug-in of the empirical frequencies.

`KL.empirical` computes the empirical Kullback-Leibler (KL) divergence from counts  $y_1$  and  $y_2$ .

`chi2.empirical` computes the empirical chi-squared statistic from counts  $y_1$  and  $y_2$ .

`mi.empirical` computes the empirical mutual information from a table of counts  $y_{2d}$ .

`chi2indep.empirical` computes the empirical chi-squared statistic of independence from a table of counts  $y_{2d}$ .

## Usage

```

freqs.empirical(y)
entropy.empirical(y, unit=c("log", "log2", "log10"))
KL.empirical(y1, y2, unit=c("log", "log2", "log10"))
chi2.empirical(y1, y2, unit=c("log", "log2", "log10"))
mi.empirical(y2d, unit=c("log", "log2", "log10"))
chi2indep.empirical(y2d, unit=c("log", "log2", "log10"))

```

## Arguments

y	vector of counts.
y1	vector of counts.
y2	vector of counts.
y2d	matrix of counts.
unit	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set <code>unit="log2"</code> .

## Details

The empirical entropy estimator is a plug-in estimator: in the definition of the Shannon entropy the bin probabilities are replaced by the respective empirical frequencies.

The empirical entropy estimator is the maximum likelihood estimator. If there are many zero counts and the sample size is small it is very inefficient and also strongly biased.

## Value

- `freqs.empirical` returns the empirical frequencies.
- `entropy.empirical` returns an estimate of the Shannon entropy.
- `KL.empirical` returns an estimate of the KL divergence.
- `chi2.empirical` returns the empirical chi-squared statistic.
- `mi.empirical` returns an estimate of the mutual information.
- `chi2indep.empirical` returns the empirical chi-squared statistic of independence.

## Author(s)

Korbinian Strimmer (<http://strimmerlab.org>).

## See Also

# empirical Kullback-Leibler divergence
KL.empirical(y1, y2)

# half of the empirical chi-squared statistic
0.5*chi2.empirical(y1, y2)

## joint distribution example

# contingency table with counts for two discrete variables
y2d = rbind( c(1,2,3), c(6,5,4) )

# empirical estimate of mutual information
mi.empirical(y2d)

# half of the empirical chi-squared statistic of independence
0.5*chi2indep.empirical(y2d)

```

`entropy.MillerMadow`    *Miller-Madow Entropy Estimator*

## Description

`entropy.MillerMadow` estimates the Shannon entropy H of the random variable Y from the corresponding observed counts y using the Miller-Madow correction to the empirical entropy).

## Usage

```
entropy.MillerMadow(y, unit=c("log", "log2", "log10"))
```

## Arguments

- |                   |  |
|-------------------|--|
| <code>y</code>    | vector of counts.  |
| <code>unit</code> | the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set <code>unit="log2"</code> . |

## Details

The Miller-Madow entropy estimator (1955) is the bias-corrected empirical entropy estimate.

Note that the Miller-Madow estimator is not a plug-in estimator, hence there are no explicit underlying bin frequencies.

## Value

`entropy.MillerMadow` returns an estimate of the Shannon entropy.

## Author(s)

Korbinian Strimmer (<http://strimmerlab.org>).

## Examples

```
# load entropy library
library("entropy")

# observed counts for each bin
y = c(4, 2, 3, 0, 2, 4, 0, 0, 2, 1, 1)

# estimate entropy using Miller-Madow method
entropy.MillerMadow(y)

# compare to empirical estimate
entropy.empirical(y)
```

## Description

`entropy.NSB` estimates the Shannon entropy  $H$  of the random variable  $Y$  from the corresponding observed counts  $y$  using the method of Nemenman, Shafee and Bialek (2002).

Note that this function is an R interface to the "nsb-entropy" program. Hence, this needs to be installed separately from <http://nsb-entropy.sourceforge.net/>.

## Usage

```
entropy.NSB(y, unit=c("log", "log2", "log10"), CMD="nsb-entropy")
```

## Arguments

y	vector of counts.
unit	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set unit="log2".
CMD	path to the "nsb-entropy" executable.

## Details

The NSB estimator is due to Nemenman, Shafee and Bialek (2002). It is a Dirichlet-multinomial entropy estimator, with a hierarchical prior over the Dirichlet pseudocount parameters.

Note that the NSB estimator is not a plug-in estimator, hence there are no explicit underlying bin frequencies.

## Value

`entropy.NSB` returns an estimate of the Shannon entropy.

## Author(s)

Jean Hausser.

---

entropy.plugin	<i>Plug-In Entropy Estimator</i>
----------------	----------------------------------

---

## Description

`entropy.plugin` computes the Shannon entropy  $H$  of a discrete random variable from the specified bin frequencies.

## Usage

```
entropy.plugin(freqs, unit=c("log", "log2", "log10"))
```

## Arguments

<code>freqs</code>	bin frequencies.
<code>unit</code>	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set <code>unit="log2"</code> .

## Details

The Shannon entropy of a discrete random variable is defined as  $H = -\sum p(x_i) \log(p(x_i))$ , where  $p(x_i)$  are the bin probabilities.

## Value

`entropy.plugin` returns the Shannon entropy.

## Author(s)

Korbinian Strimmer (<http://strimmerlab.org>).

## See Also

[entropy](#), [entropy.empirical](#), [entropy.shrink](#), [mi.plugin](#), [KL.plugin](#), [discretize](#).

## Examples

# and corresponding entropy
entropy.plugin(freqs)
```

---

`entropy.shrink`

*Shrinkage Estimators of Entropy, Mutual Information and Related Quantities*

---

## Description

`freq.shrink` estimates the bin frequencies from the counts  $y$  using a James-Stein-type shrinkage estimator, where the shrinkage target is the uniform distribution.

`entropy.shrink` estimates the Shannon entropy  $H$  of the random variable  $Y$  from the corresponding observed counts  $y$  by plug-in of shrinkage estimate of the bin frequencies.

`KL.shrink` computes a shrinkage estimate of the Kullback-Leibler (KL) divergence from counts  $y_1$  and  $y_2$ .

`chi2.shrink` computes a shrinkage version of the chi-squared statistic from counts  $y_1$  and  $y_2$ .

`mi.shrink` estimates a shrinkage estimate of mutual information of two random variables.

`chi2indep.shrink` computes a shrinkage version of the chi-squared statistic of independence from a table of counts  $y_{2d}$ .

## Usage

```
freqs.shrink(y, lambda.freqs, verbose=TRUE)
entropy.shrink(y, lambda.freqs, unit=c("log", "log2", "log10"), verbose=TRUE)
KL.shrink(y1, y2, lambda.freqs1, lambda.freqs2, unit=c("log", "log2", "log10"),
           verbose=TRUE)
chi2.shrink(y1, y2, lambda.freqs1, lambda.freqs2, unit=c("log", "log2", "log10"),
            verbose=TRUE)
mi.shrink(y2d, lambda.freqs, unit=c("log", "log2", "log10"), verbose=TRUE)
chi2indep.shrink(y2d, lambda.freqs, unit=c("log", "log2", "log10"), verbose=TRUE)
```

## Arguments

<code>y</code>	vector of counts.
<code>y1</code>	vector of counts.
<code>y2</code>	vector of counts.
<code>y2d</code>	matrix of counts.
<code>unit</code>	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set <code>unit="log2"</code> .
<code>lambda.freqs</code>	shrinkage intensity. If not specified (default) it is estimated in a James-Stein-type fashion.
<code>lambda.freqs1</code>	shrinkage intensity for first random variable. If not specified (default) it is estimated in a James-Stein-type fashion.
<code>lambda.freqs2</code>	shrinkage intensity for second random variable. If not specified (default) it is estimated in a James-Stein-type fashion.
<code>verbose</code>	report shrinkage intensity.

## Details

The shrinkage estimator is a James-Stein-type estimator. It is essentially a `entropy.Dirichlet` estimator, where the pseudocount is estimated from the data.

For details see Hausser and Strimmer (2009).

## Value

`freqs.shrink` returns a shrinkage estimate of the frequencies.

`entropy.shrink` returns a shrinkage estimate of the Shannon entropy.

`KL.shrink` returns a shrinkage estimate of the KL divergence.

`chi2.shrink` returns a shrinkage version of the chi-squared statistic.

`mi.shrink` returns a shrinkage estimate of the mutual information.

`chi2indep.shrink` returns a shrinkage version of the chi-squared statistic of independence.

In all instances the estimated shrinkage intensity is attached to the returned value as attribute `lambda.freqs`.

```
# load entropy library
library("entropy")

# a single variable

# observed counts for each bin
y = c(4, 2, 3, 0, 2, 4, 0, 0, 2, 1, 1)

# shrinkage estimate of frequencies
freqs.shrink(y)

# shrinkage estimate of entropy
entropy.shrink(y)

# example with two variables
```

```

# observed counts for two random variables
y1 = c(4, 2, 3, 1, 10, 4)
y2 = c(2, 3, 7, 1, 4, 3)

# shrinkage estimate of Kullback-Leibler divergence
KL.shrink(y1, y2)

# half of the shrinkage chi-squared statistic
0.5*chi2.shrink(y1, y2)

## joint distribution example

# contingency table with counts for two discrete variables
y2d = rbind( c(1,2,3), c(6,5,4) )

# shrinkage estimate of mutual information
mi.shrink(y2d)

# half of the shrinkage chi-squared statistic of independence
0.5*chi2indep.shrink(y2d)

```

**KL.plugin**

*Plug-In Estimator of the Kullback-Leibler divergence and of the Chi-Squared Statistic*

**Description**

`KL.plugin` computes the Kullback-Leiber (KL) divergence from random variable  $X_1$  to  $X_2$ . The corresponding probability mass functions are given by `freqs1` and `freqs2`, and the expectation is computed over `freqs1`.

`chi2.plugin` computes the chi-squared statistic between an observed  $X_1$  and an expected  $X_2$ , where `freqs1` and `freqs2` are the corresponding probability mass functions.

**Usage**

```

KL.plugin(freqs1, freqs2, unit=c("log", "log2", "log10"))
chi2.plugin(freqs1, freqs2, unit=c("log", "log2", "log10"))

```

**Arguments**

- |                     |  |
|---------------------|--|
| <code>freqs1</code> | bin frequencies for variable $X_1$ .   |
| <code>freqs2</code> | bin frequencies for variable $X_2$ .   |
| <code>unit</code>   | the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set <code>unit="log2"</code> . |

## Details

Kullback-Leibler divergence between the from random variable  $X_1$  to  $X_2$  is given as  $E_{X_1} \log(f(x_1)/f(x_2))$ .

The chi-squared statistic is given  $\sum(f(x_1) - f(x_2))^2/f(x_2)$ . It can also be seen as a second-order accurate approximation of twice the KL divergence.

Note that both the KL divergence and the chi-squared statistic are not symmetric in  $X_1$  and  $X_2$ .

## Value

`KL.plugin` returns the KL divergence.

`chi2.plugin` returns the chi-squared statistic.

## Author(s)

Korbinian Strimmer (<http://strimmerlab.org>).

## Examples

```
# load entropy library
library("entropy")

# probabilities for two random variables
freqs1 = c(1/5, 1/5, 3/5)
freqs2 = c(1/10, 4/10, 1/2)

# KL divergence from X1 to X2
KL.plugin(freqs1, freqs2)

# and corresponding (half) chi-squared statistic
0.5*chi2.plugin(freqs1, freqs2)
```

## Description

`mi.plugin` computes the mutual information of two discrete random variables from the specified joint bin frequencies.

`chi2indep.plugin` computes the chi-squared statistic of independence.

## Usage

```
mi.plugin(freqs2d, unit=c("log", "log2", "log10"))
chi2indep.plugin(freqs2d, unit=c("log", "log2", "log10"))
```

## Arguments

<code>freqs2d</code>	matrix of joint bin frequencies.
<code>unit</code>	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set <code>unit="log2"</code> .

## Details

The mutual information of two random variables  $X$  and  $Y$  is the Kullback-Leibler divergence between the joint density/probability mass function and the product independence density of the marginals.

It can also be defined using entropy as  $MI = H(X) + H(Y) - H(X, Y)$ .

Similarly, the chi-squared statistic of independence is the chi-squared statistic between the joint density and the product density. It is a second-order accurate approximation of twice the mutual information.

## Value

`mi.plugin` returns the mutual information.  
`chi2indep.plugin` returns the chi-squared statistic of independence.

## Author(s)

Korbinian Strimmer (<http://strimmerlab.org>).

## Examples

```
# load entropy library
library("entropy")

# joint distribution of two discrete variables
freqs2d = rbind( c(0.2, 0.1, 0.15), c(0.1, 0.2, 0.25) )

# corresponding mutual information
mi.plugin(freqs2d)

# MI computed via entropy
H1 = entropy.plugin(rowSums(freqs2d))
H2 = entropy.plugin(colSums(freqs2d))
H12 = entropy.plugin(freqs2d)
H1+H2-H12
```

```
# and corresponding (half) chi-squared statistic of independence  
0.5*chi2indep.plugin(freqs2d)
```
