

Package ‘eplusr’

February 20, 2020

Title A Toolkit for Using Whole Building Simulation Program
'EnergyPlus'

Version 0.12.0

Description A rich toolkit of using the whole building simulation program 'EnergyPlus'(<<https://energyplus.net>>), which enables programmatic navigation, modification of 'EnergyPlus' models and makes it less painful to do parametric simulations and analysis.

eplusr-package	<i>eplusr: A Toolkit for Using EnergyPlus in R</i>
----------------	--

Description

A rich toolkit of using the whole building simulation program 'EnergyPlus' (<<https://energyplus.net>>), which enables programmatic navigation, modification of 'EnergyPlus' models and makes it less painful to do parametric simulations and analysis.

Details

eplusr provides a rich toolkit of using EnergyPlus directly in R, which enables programmatic navigation, modification of EnergyPlus models and makes it less painful to do parametric simulations and analysis.

Features

- Download and install EnergyPlus in R
- Read, parse and modify EnergyPlus:
 - Input Data File (IDF)
 - Weather File (EPW)
 - Report Data Dictionary (RDD) & Meter Data Dictionary (MDD)
 - Error File (ERR)
- Modify multiple versions of IDFs and run corresponding EnergyPlus both in the background and in the front
- Rich-featured interfaces to query and modify IDFs
- Automatically handle referenced fields and validate input during modification
- Take fully advantage of most common used data structure for data science in R – data.frame
 - Extract model, weather data into data.frames
 - Modify multiple objects via data.frames input
 - Query output via SQL in Tidy format which is much better for data analysis and visualization
- Provide a simple yet extensible prototype of conducting parametric simulations and collect all results in one go
- A pure R-based version updater `transition()` which is much faster than VersionUpdater distributed with EnergyPlus

as.character.IddObject

Coerce an IddObject into a Character Vector

Description

Coerce an [IddObject](#) into an empty object of current class in a character vector format. It is formatted exactly the same as in IDF Editor.

Usage

```
## S3 method for class 'IddObject'
as.character(x, comment = NULL, leading = 4L, sep_at = 29L, all = FALSE, ...)
```

Arguments

x	An IddObject object.
comment	A character vector to be used as comments of returned string format object. If NULL, no comments are inserted. Default: NULL.
leading	Leading spaces added to each field. Default: 4.
sep_at	The character width to separate value string and field string. Default: 29 which is the same as IDF Editor.
all	If TRUE, all fields in current class are returned, otherwise only minimum fields are returned.
...	Further arguments passed to or from other methods.

Value

A character vector.

Examples

```
## Not run:
as.character(use_idd(8.8, download = "auto")$Material, leading = 0)

## End(Not run)
```

as.character.Idf *Coerce an Idf object into a Character Vector*

Description

Coerce an [Idf](#) object into a character vector.

Usage

```
## S3 method for class 'Idf'
as.character(
  x,
  comment = TRUE,
  header = TRUE,
  format = eplusr_option("save_format"),
  leading = 4L,
  sep_at = 29L,
  ...
)
```

Arguments

x	An Idf object.
comment	If FALSE, all comments will not be included. Default: TRUE.
header	If FALSE, the header will not be included. Default: TRUE.
format	Specific format used when formatting. For details, please see \$save(). Default: eplusr_option("save_format")
leading	Leading spaces added to each field. Default: 4L.
sep_at	The character width to separate value string and field string. Default: 29L which is the same as IDF Editor.
...	Further arguments passed to or from other methods.

Value

A character vector.

Author(s)

Hongyuan Jia

Examples

```
## Not run:
idf_path <- system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr")
as.character(read_idf(idf_path, use_idd(8.8, "auto")), leading = 0)

## End(Not run)
```

 as.character.IdfObject

Coerce an IdfObject into a Character Vector

Description

Coerce an [IdfObject](#) into a character vector in the same way as in IDF Editor.

Usage

```
## S3 method for class 'IdfObject'
as.character(x, comment = TRUE, leading = 4L, sep_at = 29L, all = FALSE, ...)
```

Arguments

x	An IdfObject object.
comment	A character vector to be used as comments of returned string format object. If NULL, no comments are inserted. Default: NULL.
leading	Leading spaces added to each field. Default: 4.
sep_at	The character width to separate value string and field string. Default: 29 which is the same as IDF Editor.
all	If TRUE, all fields in current class are returned, otherwise only minimum fields are returned.
...	Further arguments passed to or from other methods.

Value

A character vector.

Examples

```
## Not run:
idf <- read_idf(system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr"),
  idd = use_idd(8.8, download = "auto"))

# get the IdfObject of material named "C5 - 4 IN HW CONCRETE"
mat <- idf$Material[["C5 - 4 IN HW CONCRETE"]]

as.character(mat, leading = 0, sep_at = 10)

## End(Not run)
```

`clean_wd`*Clean working directory of a previous EnergyPlus simulation*

Description

Clean working directory of an EnergyPlus simulation by deleting all input and output files of previous simulation.

Usage

```
clean_wd(path)
```

Arguments

`path` An .idf or .imf file path.

Details

`clean_wd()` imitates the same process that EnergyPlus does whenever a new simulation is getting to start. It deletes all related output files that have the same name prefix as the input path. The input model itself and any weather file are not deleted. `clean_wd()` is called internally when running EnergyPlus models using `run_idf()` and `run_multi()`.

Author(s)

Hongyuan Jia

Examples

```
## Not run:
# run a test simulation
idf_path <- system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr")
epw_path <- file.path(eplus_config(8.8)$dir, "WeatherData",
  "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw")
)
dir <- file.path(tempdir(), "test")
run_idf(idf_path, epw_path, output_dir = dir, echo = FALSE)

list.files(dir)

# remove all output files
clean_wd(file.path(dir, basename(idf_path)))

list.files(dir)

## End(Not run)
```

custom_validate *Customize validation components*

Description

custom_validate() makes it easy to customize what validation components should be included during IDF object modifications using \$dup(), \$add(), \$set() and other methods in [Idf](#) class.

Usage

```
custom_validate(
  required_object = FALSE,
  unique_object = FALSE,
  unique_name = FALSE,
  extensible = FALSE,
  required_field = FALSE,
  auto_field = FALSE,
  type = FALSE,
  choice = FALSE,
  range = FALSE,
  reference = FALSE
)
```

Arguments

required_object	Check if required objects are missing in current model. Default: FALSE.
unique_object	Check if there are multiple objects in one unique-object class. Default: FALSE.
unique_name	Check if all objects in every class have unique names. Default: FALSE.
extensible	Check if all fields in an extensible group have values. Default: FALSE.
required_field	Check if all required fields have values. Default: FALSE.
auto_field	Check if all fields with value "Autosize" and "Autocalculate" are valid or not. Default: FALSE.
type	Check if all fields have values with valid types, i.e. character, numeric and integer fields should be filled with corresponding type of values. Default: FALSE.
choice	Check if all choice fields have valid choice values. Default: FALSE.
range	Check if all numeric fields have values within defined ranges. Default: FALSE.
reference	Check if all fields whose values refer to other fields are valid. Default: FALSE.

Details

There are 10 different validation check components in total. Three predefined validation level are included, i.e. "none", "draft" and "final". To get what validation components those levels contain, see [level_checks\(\)](#).

Value

A named list with 10 elements.

Examples

```
custom_validate(unique_object = TRUE)

# only check unique name during validation
eplusr_option(validate_level = custom_validate(unique_name = TRUE))
```

download_weather	<i>Download EnergyPlus Weather File (EPW) and Design Day File (DDY)</i>
------------------	---

Description

download_weather() makes it easy to download EnergyPlus weather files (EPW) and design day files (DDY).

Usage

```
download_weather(
  pattern,
  filename = NULL,
  dir = ".",
  type = c("all", "epw", "ddy"),
  ask = TRUE,
  max_match = 3
)
```

Arguments

pattern	A regular expression used to search locations, e.g. "los angeles.*tmy3". The search is case-insensitive.
filename	File names (without extension) used to save downloaded files. Internally, <code>make.unique()</code> is called to ensure unique names.
dir	Directory to save downloaded files
type	File type to download. Should be one of "all", "epw" and "ddy". If "all", both weather files and design day files will be downloaded.
ask	If TRUE, a command line menu will be shown to let you select which one to download. If FALSE and the number of returned results is less than max_match, files are downloaded automatically without asking.
max_match	The max results allowed to download when ask is FALSE.

Value

A character vector containing paths of downloaded files.

Author(s)

Hongyuan Jia

Examples

```
## Not run:
download_weather("los angeles.*tmy3", "LosAngeles", tempdir(), ask = FALSE)

## End(Not run)
```

dt_to_load

Format Long Table to Standard Input for Idf\$load() Method

Description

dt_to_load() takes a [data.table](#), usually created from [Idf\\$to_table\(\)](#) or [IdfObject\\$to_table\(\)](#) with wide being TRUE, and format it into a [data.table](#) in acceptable format for \$load() method in [Idf](#) class.

Usage

```
dt_to_load(dt, string_value = TRUE)
```

Arguments

dt	A data.table created using Idf\$to_table() and IdfObject\$to_table() . dt should at least contain column id (indicator used to distinguish object definitions), class (class names). If a name column exists, it will be preserved.
string_value	If TRUE, all value will be coerced into character and the value column of returned datat.table will be character type. If FALSE, the original value will be preserved and the value column of returned data.table will be list type.

Value

A [data.table](#) with 5 or 6 columns:

- id: Integer type. Used to distinguish each object definition.
- name: Character type. Only exists when input dt has a name column.
- class: Character type.
- index: Integer type. Field indices.
- field: Character type. Field names.
- value: Character or list type. The value of each field to be added.

Examples

```
## Not run:
# read an example distributed with eplusr
path_idf <- system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr")
idf <- read_idf(path_idf)

# extract all material object data and return it as a wide table
dt <- idf$to_table(class = "Material", wide = TRUE)

dt_to_load(dt)

## End(Not run)
```

empty_idf

Create an Empty Idf

Description

empty_idf() takes a valid IDD version and creates an empty [Idf](#) object that only contains a Version object.

Usage

```
empty_idf(ver = "latest")
```

Arguments

ver	Any acceptable input of use_idd() . If latest, which is the default, the latest IDD released version is used.
-----	---

Value

An [Idf](#) object

Examples

```
## Not run:
if (is_avail_idd(8.8)) empty_idf(8.8)

## End(Not run)
```

Description

EplusGroupJob class is a wrapper of `run_multi()` and provides an interface to group multiple EnergyPlus simulations together for running and collecting outputs.

Methods

Public methods:

- `EplusGroupJob$new()`
- `EplusGroupJob$run()`
- `EplusGroupJob$kill()`
- `EplusGroupJob$status()`
- `EplusGroupJob$errors()`
- `EplusGroupJob$output_dir()`
- `EplusGroupJob$locate_output()`
- `EplusGroupJob$list_table()`
- `EplusGroupJob$read_table()`
- `EplusGroupJob$read_rdd()`
- `EplusGroupJob$read_mdd()`
- `EplusGroupJob$report_data_dict()`
- `EplusGroupJob$report_data()`
- `EplusGroupJob$tabular_data()`
- `EplusGroupJob$print()`

Method `new()`: Create an EplusGroupJob object

Usage:

```
EplusGroupJob$new(idfs, epws)
```

Arguments:

`idfs` Paths to EnergyPlus IDF files or a list of IDF files and `Idf` objects. If only one IDF supplied, it will be used for simulations with all EPWs.

`epws` Paths to EnergyPlus EPW files or a list of EPW files and `Epw` objects. Each element in the list can be NULL, which will force design-day-only simulation. Note this needs at least one `Sizing:DesignDay` object exists in that `Idf`. If `epws` is NULL, design-day-only simulation will be conducted for all input models. If only one EPW supplied, it will be used for simulations with all IDFs.

Returns: An EplusGroupJob object.

Examples:

```

\dontrun{
if (is_avail_eplus(8.8)) {
  dir <- eplus_config(8.8)$dir
  path_idfs <- list.files(file.path(dir, "ExampleFiles"), "\\*.idf",
    full.names = TRUE)[1:5]
  path_epws <- list.files(file.path(dir, "WeatherData"), "\\*.epw",
    full.names = TRUE)[1:5]

  group <- EplusGroupJob$new(path_idfs, path_epws)
}
}

```

Method `run()`: Run grouped simulations

Usage:

```

EplusGroupJob$run(
  dir = NULL,
  wait = TRUE,
  force = FALSE,
  copy_external = FALSE,
  echo = wait
)

```

Arguments:

`dir` The parent output directory for specified simulations. Outputs of each simulation are placed in a separate folder under the parent directory.

`wait` If TRUE, R will hang on and wait all EnergyPlus simulations finish. If FALSE, all EnergyPlus simulations are run in the background. Default: TRUE.

`force` Only applicable when the last simulation runs with `wait` equals to FALSE and is still running. If TRUE, current running job is forced to stop and a new one will start. Default: FALSE.

`copy_external` If TRUE, the external files that current Idf object depends on will also be copied into the simulation output directory. The values of file paths in the Idf will be changed automatically. Currently, only `Schedule:File` class is supported. This ensures that the output directory will have all files needed for the model to run. Default is FALSE.

`echo` Only applicable when `wait` is TRUE. Whether to simulation status. Default: same as `wait`.

Details: `$run()` runs all grouped simulations in parallel. The number of parallel EnergyPlus process can be controlled by `eplusr_option("num_parallel")`. If `wait` is FALSE, then the job will be run in the background. You can get updated job status by just printing the `EplusGroupJob` object.

Returns: The `EplusGroupJob` object itself, invisibly.

Examples:

```

\dontrun{
# only run design day
group$run(NULL)

# do not show anything in the console

```

```

group$run(echo = FALSE)

# specify output directory
group$run(tempdir(), echo = FALSE)

# run in the background
group$run(wait = TRUE, echo = FALSE)
# see group job status
group$status()

# force to kill background group job before running the new one
group$run(force = TRUE, echo = FALSE)

# copy external files used in the model to simulation output directory
group$run(copy_external = TRUE, echo = FALSE)
}

```

Method kill(): Kill current running jobs

Usage:

```
EplusGroupJob$kill()
```

Details: \$kill() kills all background EnergyPlus processes that are current running if possible. It only works when simulations run in non-waiting mode.

Returns: A single logical value of TRUE or FALSE, invisibly.

Examples:

```

\dontrun{
group$kill()
}

```

Method status(): Get the group job status

Usage:

```
EplusGroupJob$status()
```

Details: \$status() returns a named list of values indicates the status of the job:

- `run_before`: TRUE if the job has been run before. FALSE otherwise.
- `alive`: TRUE if the job is still running in the background. FALSE otherwise.
- `terminated`: TRUE if the job was terminated during last simulation. FALSE otherwise. NA if the job has not been run yet.
- `successful`: TRUE if all simulations ended successfully. FALSE if there is any simulation failed. NA if the job has not been run yet.
- `changed_after`: TRUE if the *seed model* has been modified since last simulation. FALSE otherwise.
- `job_status`: A `data.table::data.table()` contains meta data for each simulation job. For details, please see `run_multi()`. If the job has not been run before, a `data.table::data.table()` with 4 columns is returned:

- `index`: The index of simulation
- `status`: The status of simulation. As the simulation has not been run, `status` will always be "idle".
- `idf`: The path of input IDF file.
- `epw`: The path of input EPW file. If not provided, NA will be assigned.

Returns: A named list of 6 elements.

Examples:

```
\dontrun{
group$status()
}
```

Method `errors()`: Read group simulation errors

Usage:

```
EplusGroupJob$errors(which = NULL, info = FALSE)
```

Arguments:

`which` An integer vector of the indexes or a character vector or names of parametric simulations.

If NULL, results of all parametric simulations are returned. Default: NULL.

`info` If FALSE, only warnings and errors are printed. Default: FALSE.

Details: `$errors()` returns a list of [ErrFile](#) objects which contain all contents of the simulation error files (.err). If `info` is FALSE, only warnings and errors are printed.

Returns: A list of [ErrFile](#) objects.

Examples:

```
\dontrun{
group$errors()

# show all information
group$errors(info = TRUE)
}
```

Method `output_dir()`: Get simulation output directory

Usage:

```
EplusGroupJob$output_dir(which = NULL)
```

Arguments:

`which` An integer vector of the indexes or a character vector or names of parametric simulations.

If NULL, results of all parametric simulations are returned. Default: NULL.

Details: `$output_dir()` returns the output directory of simulation results.

Returns: A character vector.

Examples:

```

\dontrun{
# get output directories of all simulations
group$output_dir()

# get output directories of specified simulations
group$output_dir(c(1, 4))
}

```

Method locate_output(): Get paths of output file

Usage:

```
EplusGroupJob$locate_output(which = NULL, suffix = ".err", strict = TRUE)
```

Arguments:

which An integer vector of the indexes or a character vector or names of parametric simulations.

If NULL, results of all parametric simulations are returned. Default: NULL.

suffix A string that indicates the file extension of simulation output. Default: ".err".

strict If TRUE, it will check if the simulation was terminated, is still running or the file exists or not. Default: TRUE.

Details: \$locate_output() returns the path of a single output file of specified simulations.

Returns: A character vector.

Examples:

```

\dontrun{
# get the file path of the error file
group$locate_output(c(1, 4), ".err", strict = FALSE)

# can use to detect if certain output file exists
group$locate_output(c(1, 4), ".expidf", strict = TRUE)
}

```

Method list_table(): List all table names in EnergyPlus SQL outputs

Usage:

```
EplusGroupJob$list_table(which = NULL)
```

Arguments:

which An integer vector of the indexes or a character vector or names of parametric simulations.

If NULL, results of all parametric simulations are returned. Default: NULL.

Details: \$list_table() returns a list of character vectors that contain all available table and view names in the EnergyPlus SQLite files for group simulations. The list is named using IDF names.

Returns: A named list of character vectors.

Examples:

```

\dontrun{
group$list_table(c(1, 4))
}

```

Method `read_table()`: Read the same table from EnergyPlus SQL outputs

Usage:

```
EplusGroupJob$read_table(which = NULL, name)
```

Arguments:

`which` An integer vector of the indexes or a character vector or names of parametric simulations.

If NULL, results of all parametric simulations are returned. Default: NULL.

`name` A single string specifying the name of table to read.

Details: `$read_table()` takes a simulation index and a valid table name of those from `$list_table()` and returns that table data in a `data.table::data.table()` format. The first column will always be case which can be used to distinguish output from different simulations.

Returns: A `data.table::data.table()`.

Examples:

```
\dontrun{
# read a specific table
group$read_table(c(1, 4), "Zones")
}
```

Method `read_rdd()`: Read Report Data Dictionary (RDD) files

Usage:

```
EplusGroupJob$read_rdd(which = NULL)
```

Arguments:

`which` An integer vector of the indexes or a character vector or names of parametric simulations.

If NULL, results of all parametric simulations are returned. Default: NULL.

Details: `$read_rdd()` return the core data of Report Data Dictionary (RDD) files. For details, please see `read_rdd()`. The first column will always be case which can be used to distinguish output from different simulations.

Returns: A `data.table::data.table()`.

Examples:

```
\dontrun{
group$read_rdd(c(1, 4))
}
```

Method `read_mdd()`: Read Meter Data Dictionary (MDD) files

Usage:

```
EplusGroupJob$read_mdd(which = NULL)
```

Arguments:

`which` An integer vector of the indexes or a character vector or names of parametric simulations.

If NULL, results of all parametric simulations are returned. Default: NULL.

Details: `$read_mdd()` return the core data of Meter Data Dictionary (MDD) files. For details, please see `read_mdd()`. The first column will always be case which can be used to distinguish output from different simulations.

Returns: A `data.table::data.table()`.

Examples:

```
\dontrun{
group$read_mdd(c(1, 4))
}
```

Method `report_data_dict()`: Read report data dictionary from EnergyPlus SQL outputs

Usage:

```
EplusGroupJob$report_data_dict(which = NULL)
```

Arguments:

`which` An integer vector of the indexes or a character vector or names of parametric simulations.
If NULL, results of all parametric simulations are returned. Default: NULL.

Details: `$report_data_dict()` returns a `data.table::data.table()` which contains all information about report data.

For details on the meaning of each columns, please see "2.20.2.1 ReportDataDictionary Table" in EnergyPlus "Output Details and Examples" documentation.

Returns: A `data.table::data.table()` of 10 columns:

- `case`: The model name. This column can be used to distinguish output from different simulations
- `report_data_dictionary_index`: The integer used to link the dictionary data to the variable data. Mainly useful when joining different tables
- `is_meter`: Whether report data is a meter data. Possible values: 0 and 1
- `timestep_type`: Type of data timestep. Possible values: Zone and HVAC System
- `key_value`: Key name of the data
- `name`: Actual report data name
- `reporting_frequency`:
- `schedule_name`: Name of the the schedule that controls reporting frequency.
- `units`: The data units

Examples:

```
\dontrun{
group$report_data_dict(c(1, 4))
}
```

Method `report_data()`: Read report data

Usage:

```
EplusGroupJob$report_data(
  which = NULL,
  key_value = NULL,
  name = NULL,
  year = NULL,
  tz = "UTC",
  all = FALSE,
```

```

wide = FALSE,
period = NULL,
month = NULL,
day = NULL,
hour = NULL,
minute = NULL,
interval = NULL,
simulation_days = NULL,
day_type = NULL,
environment_name = NULL
)

```

Arguments:

which An integer vector of the indexes or a character vector or names of parametric simulations.

If NULL, results of all parametric simulations are returned. Default: NULL.

key_value A character vector to identify key values of the data. If NULL, all keys of that variable will be returned. **key_value** can also be data.frame that contains **key_value** and **name** columns. In this case, **name** argument in `$report_data()` is ignored. All available **key_value** for current simulation output can be obtained using `$report_data_dict()`. Default: NULL.

name A character vector to identify names of the data. If NULL, all names of that variable will be returned. If **key_value** is a data.frame, **name** is ignored. All available **name** for current simulation output can be obtained using `$report_data_dict()`. Default: NULL.

year Year of the date time in column **datetime**. If NULL, it will calculate a year value that meets the start day of week restriction for each environment. Default: NULL.

tz Time zone of date time in column **datetime**. Default: "UTC".

all If TRUE, extra columns are also included in the returned `data.table::data.table()`.

wide If TRUE, the output is formatted in the same way as standard EnergyPlus csv output file.

period A Date or POSIXt vector used to specify which time period to return. The year value does not matter and only month, day, hour and minute value will be used when subsetting. If NULL, all time period of data is returned. Default: NULL.

month, day, hour, minute Each is an integer vector for month, day, hour, minute subsetting of **datetime** column when querying on the SQL database. If NULL, no subsetting is performed on those components. All possible month, day, hour and minute can be obtained using `$read_table(NULL, "Time")`. Default: NULL.

interval An integer vector used to specify which interval length of report to extract. If NULL, all interval will be used. Default: NULL.

simulation_days An integer vector to specify which simulation day data to extract. Note that this number resets after warmup and at the beginning of an environment period. All possible **simulation_days** can be obtained using `$read_table(NULL, "Time")`. If NULL, all simulation days will be used. Default: NULL.

day_type A character vector to specify which day type of data to extract. All possible day types are: Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, Holiday, SummerDesignDay, WinterDesignDay, CustomDay1, and CustomDay2. All possible values for current simulation output can be obtained using `$read_table(NULL, "Time")`.

environment_name A character vector to specify which environment data to extract. If NULL, all environment data are returned. Default: NULL. All possible **environment_name** for current simulation output can be obtained using:

```
$read_table(NULL, "EnvironmentPeriods")
```

case If not NULL, a character column will be added indicates the case of this simulation. If "auto", the name of the IDF file without extension is used.

Details: \$report_data() extracts the report data in a `data.table::data.table()` using key values, variable names and other specifications.

\$report_data() can also directly take all or subset output from \$report_data_dict() as input, and extract all data specified.

The returned column numbers varies depending on all argument.

- all is FALSE, the returned `data.table::data.table()` has 6 columns:
 - case: The model name. This column can be used to distinguish output from different simulations
 - datetime: The date time of simulation result
 - key_value: Key name of the data
 - name: Actual report data name
 - units: The data units
 - value: The data value
- all is TRUE, besides columns described above, extra columns are also included:
 - month: The month of reported date time
 - day: The day of month of reported date time
 - hour: The hour of reported date time
 - minute: The minute of reported date time
 - dst: Daylight saving time indicator. Possible values: 0 and 1
 - interval: Length of reporting interval
 - simulation_days: Day of simulation
 - day_type: The type of day, e.g. Monday, Tuesday and etc.
 - environment_period_index: The indices of environment.
 - environment_name: A text string identifying the environment.
 - is_meter: Whether report data is a meter data. Possible values: 0 and 1
 - type: Nature of data type with respect to state. Possible values: Sum and Avg
 - index_group: The report group, e.g. Zone, System
 - timestep_type: Type of data timestep. Possible values: Zone and HVAC System
 - reporting_frequency: The reporting frequency of the variable, e.g. HVAC System Timestep, Zone Timestep.
 - schedule_name: Name of the the schedule that controls reporting frequency.

With the datetime column, it is quite straightforward to apply time-series analysis on the simulation output. However, another painful thing is that every simulation run period has its own Day of Week for Start Day. Randomly setting the year may result in a date time series that does not have the same start day of week as specified in the RunPeriod objects.

eplusr provides a simple solution for this. By setting year to NULL, which is the default behavior, eplusr will calculate a year value (from current year backwards) for each run period that compliances with the start day of week restriction.

It is worth noting that EnergyPlus uses 24-hour clock system where 24 is only used to denote midnight at the end of a calendar day. In EnergyPlus output, "00:24:00" with a time interval being 15 mins represents a time period from "00:23:45" to "00:24:00", and similarly "00:15:00"

represents a time period from "00:24:00" to "00:15:00" of the next day. This means that if current day is Friday, day of week rule applied in schedule time period "00:23:45" to "00:24:00" (presented as "00:24:00" in the output) is also Friday, but not Saturday. However, if you try to get the day of week of time "00:24:00" in R, you will get Saturday, but not Friday. This introduces inconsistency and may cause problems when doing data analysis considering day of week value.

With wide equals TRUE, \$report_data() will format the simulation output in the same way as standard EnergyPlus csv output file. Sometimes this can be useful as there may be existing tools/workflows that depend on this format. When both wide and all are TRUE, columns of runperiod environment names and date time components are also returned, including: environment_period_index, environment_name, simulation_days, datetime, month, day, hour, minute, day_type.

For convenience, input character arguments matching in \$report_data() are **case-insensitive**.

Returns: A `data.table::data.table()`.

Examples:

```
\dontrun{
# read report data
group$report_data(c(1, 4))

# specify output variables using report data dictionary
dict <- group$report_data_dict(1)
group$report_data(c(1, 4), dict[units == "C"])

# specify output variables using 'key_value' and 'name'
group$report_data(c(1, 4), "environment", "site outdoor air drybulb temperature")

# explicitly specify year value and time zone
group$report_data(c(1, 4), dict[1], year = 2020, tz = "Etc/GMT+8")

# get all possible columns
group$report_data(c(1, 4), dict[1], all = TRUE)

# return in a format that is similar as EnergyPlus CSV output
group$report_data(c(1, 4), dict[1], wide = TRUE)

# return in a format that is similar as EnergyPlus CSV output with
# extra columns
group$report_data(c(1, 4), dict[1], wide = TRUE, all = TRUE)

# only get data at the working hour on the first Monday
group$report_data(c(1, 4), dict[1], hour = 8:18, day_type = "monday", simulation_days = 1:7)
}
```

Method tabular_data(): Read tabular data

Usage:

```
EplusGroupJob$tabular_data(
```

```

which = NULL,
report_name = NULL,
report_for = NULL,
table_name = NULL,
column_name = NULL,
row_name = NULL,
wide = FALSE,
string_value = !wide
)

```

Arguments:

`which` An integer vector of the indexes or a character vector or names of parametric simulations.

If NULL, results of all parametric simulations are returned. Default: NULL.

`report_name`, `report_for`, `table_name`, `column_name`, `row_name` Each is a character vector for subsetting when querying the SQL database. For the meaning of each argument, please see the description above.

`wide` If TRUE, each table will be converted into the similar format as it is shown in EnergyPlus HTML output file. Default: FALSE.

`string_value` Only applicable when `wide` is TRUE. If `string_value` is FALSE, instead of keeping all values as characters, values in possible numeric columns are converted into numbers. Default: the opposite of `wide`. Possible numeric columns indicate column that:

- columns that have associated units
- columns that contents numbers

Details: `$tabular_data()` extracts the tabular data in a `data.table::data.table()` using `report`, `table`, `column` and `row` name specifications. The returned `data.table::data.table()` has 9 columns:

- `case`: The model name. This column can be used to distinguish output from different simulations
- `index`: Tabular data index
- `report_name`: The name of the report that the record belongs to
- `report_for`: The For text that is associated with the record
- `table_name`: The name of the table that the record belongs to
- `column_name`: The name of the column that the record belongs to
- `row_name`: The name of the row that the record belongs to
- `units`: The units of the record
- `value`: The value of the record **in string format** by default

For convenience, input character arguments matching in `$tabular_data()` are **case-insensitive**.

Returns: A `data.table::data.table()` with 9 columns (when `wide` is FALSE) or a named list of `data.table::data.table()`s where the names are the combination of `report_name`, `report_for` and `table_name`.

Examples:

```

\dontrun{
# read all tabular data
group$tabular_data(c(1, 4))

```

```

# explicitly specify data you want
str(group$tabular_data(c(1, 4),
  report_name = "AnnualBuildingUtilityPerformanceSummary",
  table_name = "Site and Source Energy",
  column_name = "Total Energy",
  row_name = "Total Site Energy"
))

# get tabular data in wide format and coerce numeric values
str(group$tabular_data(c(1, 4),
  report_name = "AnnualBuildingUtilityPerformanceSummary",
  table_name = "Site and Source Energy",
  column_name = "Total Energy",
  row_name = "Total Site Energy",
  wide = TRUE, string_value = FALSE
))
}

```

Method print(): Print EplusGroupJob object

Usage:

```
EplusGroupJob$print()
```

Details: \$print() shows the core information of this EplusGroupJob, including the path of IDFs and EPWs and also the simulation job status.

\$print() is quite useful to get the simulation status, especially when wait is FALSE in \$run(). The job status will be updated and printed whenever \$print() is called.

Returns: The EplusGroupJob object itself, invisibly.

Examples:

```

\dontrun{
group$print()
}

```

EplusJob

Run EnergyPlus Simulation and Collect Outputs

Description

EplusJob class wraps the EnergyPlus command line interface and provides methods to extract simulation outputs.

Details

eplusr uses the EnergyPlus SQL output for extracting simulation outputs. EplusJob has provide some wrappers that do SQL query to get report data results, i.e. results from `Output:Variable` and `Output:Meter*`. But for `Output:Table` results, you have to be familiar with the structure of the EnergyPlus SQL results, especially for table *"TabularDataWithStrings"*. For details, please see *"2.20 eplusout.sql"*, especially *"2.20.4.4 TabularData Table"* in EnergyPlus *"Output Details and Examples"* documentation. An object in `Output:SQLite` with `Option Type` value of `SimpleAndTabular` will be automatically created if it does not exists, to ensure that the output collection functionality works successfully.

In order to make sure `.rdd` (Report Data Dictionary) and `.mdd` (Meter Data Dictionary) files are created during simulation, an object in `Output:VariableDictionary` class with `Key Field` value being `IDF` will be automatically created if it does not exists.

Methods

Public methods:

- [EplusJob\\$new\(\)](#)
- [EplusJob\\$version\(\)](#)
- [EplusJob\\$path\(\)](#)
- [EplusJob\\$run\(\)](#)
- [EplusJob\\$kill\(\)](#)
- [EplusJob\\$status\(\)](#)
- [EplusJob\\$errors\(\)](#)
- [EplusJob\\$output_dir\(\)](#)
- [EplusJob\\$locate_output\(\)](#)
- [EplusJob\\$read_rdd\(\)](#)
- [EplusJob\\$read_mdd\(\)](#)

- `EplusJob$list_table()`
- `EplusJob$read_table()`
- `EplusJob$report_data_dict()`
- `EplusJob$report_data()`
- `EplusJob$tabular_data()`
- `EplusJob$print()`

Method new(): Create an EplusJob object

Usage:

```
EplusJob$new(idf, epw)
```

Arguments:

idf Path to a local EnergyPlus IDF file or an [Idf](#) object.

epw Path to a local EnergyPlus EPW file or an [Epw](#) object.

Returns: An EplusJob object.

Examples:

```
if (is_avail_eplus(8.8)) {
  idf_name <- "1ZoneUncontrolled.idf"
  epw_name <- "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"

  idf_path <- file.path(eplus_config(8.8)$dir, "ExampleFiles", idf_name)
  epw_path <- file.path(eplus_config(8.8)$dir, "WeatherData", epw_name)

  job <- EplusJob$new(idf_path, epw_path)
}
```

Method version(): Get the version of IDF in current job

Usage:

```
EplusJob$version()
```

Details: \$version() returns the version of IDF that current EplusJob uses.

Returns: A `base::numeric_version()` object.

Examples:

```
\dontrun{
job$version()
}
```

Method path(): Get the paths of file that current EpwSql uses

Usage:

```
EplusJob$path(type = c("all", "idf", "epw"))
```

Arguments:

type If "all", both the [Idf](#) path and [Epw](#) path are returned. If "idf", only IDF path is returned.

If "epw", only EPW path is returned. If epw is NULL, NA is returned for EPW path. Default: "all".

Details: \$path() returns the path of IDF or EPW of current job.

Returns: A character vector.

Examples:

```
\dontrun{
job$path()
job$path("idf")
job$path("epw")
}
```

Method run(): Run simulationA

Usage:

```
EplusJob$run(
  epw,
  dir = NULL,
  wait = TRUE,
  force = FALSE,
  echo = wait,
  copy_external = FALSE
)
```

Arguments:

epw A path to an .epw file or an [Epw](#) object. epw can also be NULL which will force design-day-only simulation. Note this needs at least one Sizing:DesignDay object exists in the Idf. If not given, the epw input used when creating this EplusJob object will be used.

dir The directory to save the simulation results. If NULL, the input idf folder will be used. Default: NULL.

wait If TRUE, R will hang on and wait for the simulation to complete. EnergyPlus standard output (stdout) and error (stderr) is printed to R console. If FALSE, simulation will be run in a background process. Default: TRUE.

force Only applicable when the last job runs with wait equals to FALSE and is still running. If TRUE, current running job is forced to stop and a new one will start. Default: FALSE.

echo Only applicable when wait is TRUE. Whether to show standard output and error from EnergyPlus. Default: same as wait.

copy_external If TRUE, the external files that current Idf object depends on will also be copied into the simulation output directory. The values of file paths in the Idf will be changed automatically. Currently, only Schedule:File class is supported. This ensures that the output directory will have all files needed for the model to run. Default is FALSE.

Details: \$run() runs the simulation using input IDF and EPW file. If wait is FALSE, the job is run in the background. You can get updated job status by just **printing** the EplusJob object.

Parameter epw can be used to reset the EPW file to use for simulation. If not given, the epw input used when creating this EplusJob object will be used.

Returns: The EplusJob object itself, invisibly.

Examples:

```
\dontrun{
# only run design day
job$run(NULL)

# specify output directory
job$run(dir = tempdir())

# run in the background
job$run(wait = TRUE)
# see job status
job$status()

# force to kill background job before running the new one
job$run(force = TRUE)

# do not show anything in the console
job$run(echo = FALSE)

# copy external files used in the model to simulation output directory
job$run(copy_external = TRUE)
}
```

Method kill(): Kill current running job

Usage:

```
EplusJob$kill()
```

Details: \$kill() kills the background EnergyPlus process if possible. It only works when simulation runs in non-waiting mode.

Returns: A single logical value of TRUE or FALSE, invisibly.

Examples:

```
\dontrun{
job$kill()
}
```

Method status(): Get the job status

Usage:

```
EplusJob$status()
```

Details: \$status() returns a named list of values that indicates the status of the job:

- run_before: TRUE if the job has been run before. FALSE otherwise.
- alive: TRUE if the simulation is still running in the background. FALSE otherwise.
- terminated: TRUE if the simulation was terminated during last simulation. FALSE otherwise. NA if the job has not been run yet.
- successful: TRUE if last simulation ended successfully. FALSE otherwise. NA if the job has not been run yet.

- `changed_after`: TRUE if the IDF file has been changed since last simulation. FALSE otherwise. NA if the job has not been run yet.

Returns: A named list of 5 elements.

Examples:

```
\dontrun{
job$status()
}
```

Method `errors()`: Read simulation errors

Usage:

```
EplusJob$errors(info = FALSE)
```

Arguments:

`info` If FALSE, only warnings and errors are printed. Default: FALSE.

Details: `$errors()` returns an [ErrFile](#) object which contains all contents of the simulation error file (`.err`). If `info` is FALSE, only warnings and errors are printed.

Returns: An [ErrFile](#) object.

Examples:

```
\dontrun{
job$errors()

# show all information
job$errors(info = TRUE)
}
```

Method `output_dir()`: Get simulation output directory

Usage:

```
EplusJob$output_dir(open = FALSE)
```

Arguments:

`open` If TRUE, the output directory will be opened.

Details: `$output_dir()` returns the output directory of simulation results.

Examples:

```
\dontrun{
job$output_dir()

# open output directory
job$output_dir(open = TRUE)
}
```

Method `locate_output()`: Get path of output file

Usage:

```
EplusJob$locate_output(suffix = ".err", strict = TRUE)
```

Arguments:

suffix A string that indicates the file extension of simulation output. Default: ".err".
strict If TRUE, it will check if the simulation was terminated, is still running or the file exists or not. Default: TRUE.

Details: \$locate_output() returns the path of a single output file specified by file suffix.

Examples:

```
\dontrun{
# get the file path of the error file
job$locate_output(".err", strict = FALSE)

# can use to detect if certain output file exists
job$locate_output(".expidf", strict = TRUE)
}
```

Method read_rdd(): Read Report Data Dictionary (RDD) file

Usage:

```
EplusJob$read_rdd()
```

Details: \$read_rdd() return the core data of Report Data Dictionary (RDD) file. For details, please see [read_rdd\(\)](#).

Returns: An [RddFile](#) object.

Examples:

```
\dontrun{
job$read_rdd()
}
```

Method read_mdd(): Read Report Data Dictionary (RDD) file

Usage:

```
EplusJob$read_mdd()
```

Details: \$read_mdd() return the core data of Meter Data Dictionary (MDD) file. For details, please see [read_mdd\(\)](#).

Returns: An [MddFile](#) object.

Examples:

```
\dontrun{
job$read_mdd()
}
```

Method list_table(): List all table names in EnergyPlus SQL output

Usage:

```
EplusJob$list_table()
```

Details: \$list_table() returns all available table and view names in the EnergyPlus SQLite file.

Returns: A character vector

Examples:

```
\dontrun{
job$list_table()
}
```

Method read_table(): Read a single table from EnergyPlus SQL output

Usage:

```
EplusJob$read_table(name)
```

Arguments:

name A single string specifying the name of table to read.

Details: \$read_table() takes a valid table name of those from \$list_table() and returns that table data in a `data.table::data.table()` format.

Returns: A `data.table::data.table()`.

Examples:

```
\dontrun{
# read a specific table
job$read_table("Zones")
}
```

Method report_data_dict(): Read report data dictionary from EnergyPlus SQL output

Usage:

```
EplusJob$report_data_dict()
```

Details: \$report_data_dict() returns a `data.table::data.table()` which contains all information about report data.

For details on the meaning of each columns, please see "2.20.2.1 ReportDataDictionary Table" in EnergyPlus "Output Details and Examples" documentation.

Returns: A `data.table::data.table()` of 10 columns:

- report_data_dictionary_index: The integer used to link the dictionary data to the variable data. Mainly useful when joining different tables
- is_meter: Whether report data is a meter data. Possible values: 0 and 1
- timestep_type: Type of data timestep. Possible values: Zone and HVAC System
- key_value: Key name of the data
- name: Actual report data name
- reporting_frequency:
- schedule_name: Name of the the schedule that controls reporting frequency.
- units: The data units

Examples:

```

\dontrun{
job$report_data_dict()
}

```

Method `report_data()`: Read report data

Usage:

```

EplusJob$report_data(
  key_value = NULL,
  name = NULL,
  year = NULL,
  tz = "UTC",
  case = "auto",
  all = FALSE,
  wide = FALSE,
  period = NULL,
  month = NULL,
  day = NULL,
  hour = NULL,
  minute = NULL,
  interval = NULL,
  simulation_days = NULL,
  day_type = NULL,
  environment_name = NULL
)

```

Arguments:

`key_value` A character vector to identify key values of the data. If NULL, all keys of that variable will be returned. `key_value` can also be `data.frame` that contains `key_value` and `name` columns. In this case, `name` argument in `$report_data()` is ignored. All available `key_value` for current simulation output can be obtained using `$report_data_dict()`. Default: NULL.

`name` A character vector to identify names of the data. If NULL, all names of that variable will be returned. If `key_value` is a `data.frame`, `name` is ignored. All available `name` for current simulation output can be obtained using `$report_data_dict()`. Default: NULL.

`year` Year of the date time in column `datetime`. If NULL, it will calculate a year value that meets the start day of week restriction for each environment. Default: NULL.

`tz` Time zone of date time in column `datetime`. Default: "UTC".

`case` If not NULL, a character column will be added indicates the case of this simulation. If "auto", the name of the IDF file without extension is used.

`all` If TRUE, extra columns are also included in the returned `data.table::data.table()`.

`wide` If TRUE, the output is formatted in the same way as standard EnergyPlus csv output file.

`period` A Date or POSIXt vector used to specify which time period to return. The year value does not matter and only month, day, hour and minute value will be used when subsetting. If NULL, all time period of data is returned. Default: NULL.

`month`, `day`, `hour`, `minute` Each is an integer vector for month, day, hour, minute subsetting of `datetime` column when querying on the SQL database. If NULL, no subsetting is performed

on those components. All possible month, day, hour and minute can be obtained using `$read_table("Time")`. Default: NULL.

`interval` An integer vector used to specify which interval length of report to extract. If NULL, all interval will be used. Default: NULL.

`simulation_days` An integer vector to specify which simulation day data to extract. Note that this number resets after warmup and at the beginning of an environment period. All possible `simulation_days` can be obtained using `$read_table("Time")`. If NULL, all simulation days will be used. Default: NULL.

`day_type` A character vector to specify which day type of data to extract. All possible day types are: Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, Holiday, SummerDesignDay, WinterDesignDay, CustomDay1, and CustomDay2. All possible values for current simulation output can be obtained using `$read_table("Time")`.

`environment_name` A character vector to specify which environment data to extract. If NULL, all environment data are returned. Default: NULL. All possible `environment_name` for current simulation output can be obtained using:

```
$read_table("EnvironmentPeriods")
```

Details: `$report_data()` extracts the report data in a `data.table::data.table()` using key values, variable names and other specifications.

`$report_data()` can also directly take all or subset output from `$report_data_dict()` as input, and extract all data specified.

The returned column numbers varies depending on `all` argument.

- `all` is FALSE, the returned `data.table::data.table()` has 6 columns:
 - `case`: Simulation case specified using `case` argument
 - `datetime`: The date time of simulation result
 - `key_value`: Key name of the data
 - `name`: Actual report data name
 - `units`: The data units
 - `value`: The data value
- `all` is TRUE, besides columns described above, extra columns are also included:
 - `month`: The month of reported date time
 - `day`: The day of month of reported date time
 - `hour`: The hour of reported date time
 - `minute`: The minute of reported date time
 - `dst`: Daylight saving time indicator. Possible values: 0 and 1
 - `interval`: Length of reporting interval
 - `simulation_days`: Day of simulation
 - `day_type`: The type of day, e.g. Monday, Tuesday and etc.
 - `environment_period_index`: The indices of environment.
 - `environment_name`: A text string identifying the environment.
 - `is_meter`: Whether report data is a meter data. Possible values: 0 and 1
 - `type`: Nature of data type with respect to state. Possible values: Sum and Avg
 - `index_group`: The report group, e.g. Zone, System
 - `timestep_type`: Type of data timestep. Possible values: Zone and HVAC System

- `reporting_frequency`: The reporting frequency of the variable, e.g. HVAC System Timestep, Zone Timestep.
- `schedule_name`: Name of the the schedule that controls reporting frequency.

With the `datetime` column, it is quite straightforward to apply time-series analysis on the simulation output. However, another painful thing is that every simulation run period has its own Day of Week for Start Day. Randomly setting the year may result in a date time series that does not have the same start day of week as specified in the RunPeriod objects.

`eplusr` provides a simple solution for this. By setting `year` to `NULL`, which is the default behavior, `eplusr` will calculate a year value (from current year backwards) for each run period that compliances with the start day of week restriction.

It is worth noting that EnergyPlus uses 24-hour clock system where 24 is only used to denote midnight at the end of a calendar day. In EnergyPlus output, "00:24:00" with a time interval being 15 mins represents a time period from "00:23:45" to "00:24:00", and similarly "00:15:00" represents a time period from "00:24:00" to "00:15:00" of the next day. This means that if current day is Friday, day of week rule applied in schedule time period "00:23:45" to "00:24:00" (presented as "00:24:00" in the output) is also Friday, but not Saturday. However, if you try to get the day of week of time "00:24:00" in R, you will get Saturday, but not Friday. This introduces inconsistency and may cause problems when doing data analysis considering day of week value.

With `wide` equals `TRUE`, `$report_data()` will format the simulation output in the same way as standard EnergyPlus csv output file. Sometimes this can be useful as there may be existing tools/workflows that depend on this format. When both `wide` and `all` are `TRUE`, columns of runperiod environment names and date time components are also returned, including: `environment_period_index`, `environment_name`, `simulation_days`, `datetime`, `month`, `day`, `hour`, `minute`, `day_type`.

For convenience, input character arguments matching in `$report_data()` are **case-insensitive**.

Returns: A `data.table::data.table()`.

Examples:

```
\dontrun{
# read all report data
job$report_data()

# specify output variables using report data dictionary
dict <- job$report_data_dict()
job$report_data(dict[units == "C"])

# specify output variables using 'key_value' and 'name'
job$report_data("environment", "site outdoor air drybulb temperature")

# explicitly specify year value and time zone
job$report_data(dict[1], year = 2020, tz = "Etc/GMT+8")

# explicitly specify case name
job$report_data(dict[1], case = "example")

# get all possible columns
job$report_data(dict[1], all = TRUE)
```

```

# return in a format that is similar as EnergyPlus CSV output
job$report_data(dict[1], wide = TRUE)

# return in a format that is similar as EnergyPlus CSV output with
# extra columns
job$report_data(dict[1], wide = TRUE, all = TRUE)

# only get data at the working hour on the first Monday
job$report_data(dict[1], hour = 8:18, day_type = "monday", simulation_days = 1:7)

# only get specified run period data
job$read_table("EnvironmentPeriods") # possible environment name
job$report_data(dict[1], environment_name = "San Francisco Intl Ap CA USA TMY3 WMO#=724940")
# can also be done using 'environment_period_index' column
job$report_data(dict[1], all = TRUE)[environment_period_index == 3L]
}

```

Method `tabular_data()`: Read tabular data

Usage:

```

EplusJob$tabular_data(
  report_name = NULL,
  report_for = NULL,
  table_name = NULL,
  column_name = NULL,
  row_name = NULL,
  wide = FALSE,
  string_value = !wide
)

```

Arguments:

`report_name`, `report_for`, `table_name`, `column_name`, `row_name` Each is a character vector for subsetting when querying the SQL database. For the meaning of each argument, please see the description above.

`wide` If TRUE, each table will be converted into the similar format as it is shown in EnergyPlus HTML output file. Default: FALSE.

`string_value` Only applicable when `wide` is TRUE. If `string_value` is FALSE, instead of keeping all values as characters, values in possible numeric columns are converted into numbers.

Default: the opposite of `wide`. Possible numeric columns indicate column that:

- columns that have associated units
- columns that contents numbers

Details: `$tabular_data()` extracts the tabular data in a `data.table::data.table()` using `report`, `table`, `column` and `row name` specifications. The returned `data.table::data.table()` has 9 columns:

- `case`: Simulation case specified using `case` argument
- `index`: Tabular data index
- `report_name`: The name of the report that the record belongs to

- `report_for`: The For text that is associated with the record
- `table_name`: The name of the table that the record belongs to
- `column_name`: The name of the column that the record belongs to
- `row_name`: The name of the row that the record belongs to
- `units`: The units of the record
- `value`: The value of the record **in string format** by default

For convenience, input character arguments matching in `$tabular_data()` are **case-insensitive**.

Returns: A `data.table::data.table()` with 8 columns (when `wide` is `FALSE`) or a named list of `data.table::data.table()`s where the names are the combination of `report_name`, `report_for` and `table_name`.

Examples:

```
\dontrun{
# read all tabular data
job$tabular_data()

# explicitly specify data you want
str(job$tabular_data(
  report_name = "AnnualBuildingUtilityPerformanceSummary",
  table_name = "Site and Source Energy",
  column_name = "Total Energy",
  row_name = "Total Site Energy"
))

# get tabular data in wide format and coerce numeric values
str(job$tabular_data(
  report_name = "AnnualBuildingUtilityPerformanceSummary",
  table_name = "Site and Source Energy",
  column_name = "Total Energy",
  row_name = "Total Site Energy",
  wide = TRUE, string_value = FALSE
))
}
```

Method `print()`: Print `EplusSql` object

Usage:

```
EplusJob$print()
```

Details: `$print()` shows the core information of this `EplusJob` object, including the path of model and weather, the version and path of EnergyPlus used to run simulations, and the simulation job status.

`$print()` is quite useful to get the simulation status, especially when `wait` is `FALSE` in `$run()`. The job status will be updated and printed whenever `$print()` is called.

Returns: The `EplusSql` object itself, invisibly.

Examples:

```

\dontrun{
job$print()
}

```

eplusr_option

Get and Set eplusr options

Description

Get and set eplusr options which affect the way in which eplusr computes and displays its results.

Usage

```
eplusr_option(...)
```

Arguments

... Any available options to define, using name = value. All available options are shown below. If no options are given, all values of current options are returned. If a single option name, its value is returned.

Details

- `validate_level`: The strictness level of validation during field value modification and model error checking. Possible value: "none", "draft" and "final" or a custom validation level using `custom_validate()`. Default: "final". For what validation components each level contains, see `level_checks()`.
- `view_in_ip`: Whether models should be presented in IP units. Default: FALSE. It is not recommended to set this option to TRUE as currently IP-units support in eplusr is not fully tested.
- `save_format`: The default format to use when saving `Idf` objects to `.idf` files. Possible values: "asis", "sorted", "new_top" and "new_bottom". The later three have the same effect as Save Options settings "Sorted", "Original with New at Top" and "Original with New at Bottom" in IDF Editor, respectively. For "asis", the saving format will be set according to the header of IDF file. If no header found, "sorted" is used. Default: "asis".
- `num_parallel`: Maximum number of parallel simulations to run. Default: `parallel::detectCores()`.
- `verbose_info`: Whether to show information messages. Default: TRUE.
- `autocomplete`: Whether to turn on autocompletion on class and field names. Underneath, `makeActiveBinding()` is used to add or move active bindings in `Idf` and `IdfObjects` to directly return objects in class or field values. This will make it possible to dynamically show current class and field names in both RStudio and in the terminal. However, this process does have a penalty on the performance. It can make adding or modifying large mounts of `Idf` and `IdfObjects` extremely slower. Default: `interactive()`.

Value

If called directly, a named list of input option values. If input is a single option name, a length-one vector whose type is determined by that option. If input is new option values, a named list of newly set option values.

Author(s)

Hongyuan Jia

Examples

```
# list all current options
eplusr_option() # a named list

# get a specific option value
eplusr_option("verbose_info")

# set options
eplusr_option(verbose_info = TRUE, view_in_ip = FALSE)
```

EplusSql

Retrieve Simulation Outputs Using EnergyPlus SQLite Output File

Description

EplusSql class wraps SQL queries that can retrieve simulation outputs using EnergyPlus SQLite output file.

Details

SQLite output is an optional output format for EnergyPlus. It will be created if there is an object in class `Output:SQLite`. If the value of field `Option` in class `Output:SQLite` is set to "SimpleAndTabular", then database tables related to the tabular reports will be also included.

There are more than 30 tables in the SQLite output file which contains all of the data found in EnergyPlus's tabular output files, standard variable and meter output files, plus a number of reports that are found in the `eplusout.eio` output file. The full description for SQLite outputs can be found in the EnergyPlus "*Output Details and Examples*" documentation. Note that all column names of tables returned have been tidied, i.e. "KeyValue" becomes "key_value", "IsMeter" becomes "is_meter" and etc.

EplusSql class makes it possible to directly retrieve simulation results without creating an [EplusJob](#) object. [EplusJob](#) can only get simulation outputs after the job was successfully run before.

However, it should be noted that, unlike [EplusJob](#), there is no checking on whether the simulation is terminated or completed unsuccessfully or, the parent `Idf` has been changed since last simulation. This means that you may encounter some problems when retrieve data from an unsuccessful simulation. It is suggested to carefully go through the `.err` file using `read_err()` to make sure the output data in the SQLite is correct and reliable.

Methods**Public methods:**

- [EplusSql\\$new\(\)](#)
- [EplusSql\\$path\(\)](#)
- [EplusSql\\$path_idf\(\)](#)
- [EplusSql\\$list_table\(\)](#)
- [EplusSql\\$read_table\(\)](#)
- [EplusSql\\$report_data_dict\(\)](#)
- [EplusSql\\$report_data\(\)](#)
- [EplusSql\\$tabular_data\(\)](#)
- [EplusSql\\$print\(\)](#)

Method new(): Create an EplusSql object

Usage:

```
EplusSql$new(sql)
```

Arguments:

sql A path to an local EnergyPlus SQLite output file.

Returns: An EplusSql object.

Examples:

```
\dontrun{
if (is_avail_eplus(8.8)) {
  idf_name <- "1ZoneUncontrolled.idf"
  epw_name <- "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"

  idf_path <- file.path(eplus_config(8.8)$dir, "ExampleFiles", idf_name)
  epw_path <- file.path(eplus_config(8.8)$dir, "WeatherData", epw_name)

  # copy to tempdir and run the model
  idf <- read_idf(idf_path)
  idf$run(epw_path, tempdir(), echo = FALSE)

  # create from local file
  sql <- eplus_sql(file.path(tempdir(), "1ZoneUncontrolled.sql"))
}
}
```

Method path(): Get the file path of current EplusSql object

Usage:

```
EplusSql$path()
```

Details: \$path() returns the path of EnergyPlus SQLite file.

Returns: A single string.

Examples:

```
\dontrun{
# get path
sql$path()
}
```

Method `path_idf()`: Get the path of corresponding IDF file

Usage:

```
EplusSql$path_idf()
```

Details: `$path_idf()` returns the IDF file path with same name as the SQLite file in the same folder. NULL is returned if no corresponding IDF is found.

Returns: NULL or a single string.

Examples:

```
\dontrun{
# get path
sql$path_idf()
}
```

Method `list_table()`: List all table names in current EnergyPlus SQL output

Usage:

```
EplusSql$list_table()
```

Details: `$list_table()` returns all available table and view names in the EnergyPlus SQLite file.

Returns: A character vector

Examples:

```
\dontrun{
sql$list_table()
}
```

Method `read_table()`: Read a single table from current EnergyPlus SQL output

Usage:

```
EplusSql$read_table(name)
```

Arguments:

`name` A single string specifying the name of table to read.

Details: `$read_table()` takes a valid table name of those from `$list_table()` and returns that table data in a `data.table::data.table()` format.

Returns: A `data.table::data.table()`.

Examples:

```
\dontrun{
# read a specific table
sql$read_table("Zones")
}
```

Method `report_data_dict()`: Read report data dictionary from current EnergyPlus SQL output

Usage:

```
EplusSql$report_data_dict()
```

Details: `$report_data_dict()` returns a `data.table::data.table()` which contains all information about report data.

For details on the meaning of each columns, please see "2.20.2.1 ReportDataDictionary Table" in EnergyPlus "Output Details and Examples" documentation.

Returns: A `data.table::data.table()` of 10 columns:

- `report_data_dictionary_index`: The integer used to link the dictionary data to the variable data. Mainly useful when joining different tables
- `is_meter`: Whether report data is a meter data. Possible values: 0 and 1
- `timestep_type`: Type of data timestep. Possible values: Zone and HVAC System
- `key_value`: Key name of the data
- `name`: Actual report data name
- `reporting_frequency`:
- `schedule_name`: Name of the the schedule that controls reporting frequency.
- `units`: The data units

Examples:

```
\dontrun{
sql$report_data_dict()
}
```

Method `report_data()`: Read report data

Usage:

```
EplusSql$report_data(
  key_value = NULL,
  name = NULL,
  year = NULL,
  tz = "UTC",
  case = "auto",
  all = FALSE,
  wide = FALSE,
  period = NULL,
  month = NULL,
  day = NULL,
  hour = NULL,
  minute = NULL,
  interval = NULL,
  simulation_days = NULL,
  day_type = NULL,
  environment_name = NULL
)
```

Arguments:

key_value A character vector to identify key values of the data. If NULL, all keys of that variable will be returned. **key_value** can also be `data.frame` that contains **key_value** and **name** columns. In this case, **name** argument in `$report_data()` is ignored. All available **key_value** for current simulation output can be obtained using `$report_data_dict()`. Default: NULL.

name A character vector to identify names of the data. If NULL, all names of that variable will be returned. If **key_value** is a `data.frame`, **name** is ignored. All available **name** for current simulation output can be obtained using `$report_data_dict()`. Default: NULL.

year Year of the date time in column `datetime`. If NULL, it will calculate a year value that meets the start day of week restriction for each environment. Default: NULL.

tz Time zone of date time in column `datetime`. Default: "UTC".

case A single string used to add a character column **case** in the returned results to indicate the case of this simulation. If NULL, no column is added. If "auto", the name of the IDF file without extension is used. Default: "auto".

all If TRUE, extra columns are also included in the returned `data.table::data.table()`.

wide If TRUE, the output is formatted in the same way as standard EnergyPlus csv output file.

period A Date or POSIXt vector used to specify which time period to return. The year value does not matter and only month, day, hour and minute value will be used when subsetting. If NULL, all time period of data is returned. Default: NULL.

month, day, hour, minute Each is an integer vector for month, day, hour, minute subsetting of `datetime` column when querying on the SQL database. If NULL, no subsetting is performed on those components. All possible month, day, hour and minute can be obtained using `$read_table("Time")`. Default: NULL.

interval An integer vector used to specify which interval length of report to extract. If NULL, all interval will be used. Default: NULL.

simulation_days An integer vector to specify which simulation day data to extract. Note that this number resets after warmup and at the beginning of an environment period. All possible **simulation_days** can be obtained using `$read_table("Time")`. If NULL, all simulation days will be used. Default: NULL.

day_type A character vector to specify which day type of data to extract. All possible day types are: Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, Holiday, SummerDesignDay, WinterDesignDay, CustomDay1, and CustomDay2. All possible values for current simulation output can be obtained using `$read_table("Time")`.

environment_name A character vector to specify which environment data to extract. If NULL, all environment data are returned. Default: NULL. All possible **environment_name** for current simulation output can be obtained using:
`$read_table("EnvironmentPeriods")`

Details: `$report_data()` extracts the report data in a `data.table::data.table()` using key values, variable names and other specifications.

`$report_data()` can also directly take all or subset output from `$report_data_dict()` as input, and extract all data specified.

The returned column numbers varies depending on **all** argument.

- **all** is FALSE, the returned `data.table::data.table()` has 6 columns:
 - **case**: Simulation case specified using **case** argument
 - **datetime**: The date time of simulation result
 - **key_value**: Key name of the data

- name: Actual report data name
- units: The data units
- value: The data value
- all is TRUE, besides columns described above, extra columns are also included:
 - month: The month of reported date time
 - day: The day of month of reported date time
 - hour: The hour of reported date time
 - minute: The minute of reported date time
 - dst: Daylight saving time indicator. Possible values: 0 and 1
 - interval: Length of reporting interval
 - simulation_days: Day of simulation
 - day_type: The type of day, e.g. Monday, Tuesday and etc.
 - environment_period_index: The indices of environment.
 - environment_name: A text string identifying the environment.
 - is_meter: Whether report data is a meter data. Possible values: 0 and 1
 - type: Nature of data type with respect to state. Possible values: Sum and Avg
 - index_group: The report group, e.g. Zone, System
 - timestep_type: Type of data timestep. Possible values: Zone and HVAC System
 - reporting_frequency: The reporting frequency of the variable, e.g. HVAC System Timestep, Zone Timestep.
 - schedule_name: Name of the the schedule that controls reporting frequency.

With the `datetime` column, it is quite straightforward to apply time-series analysis on the simulation output. However, another painful thing is that every simulation run period has its own Day of Week for Start Day. Randomly setting the year may result in a date time series that does not have the same start day of week as specified in the `RunPeriod` objects.

`eplusr` provides a simple solution for this. By setting `year` to `NULL`, which is the default behavior, `eplusr` will calculate a year value (from current year backwards) for each run period that compliances with the start day of week restriction.

It is worth noting that EnergyPlus uses 24-hour clock system where 24 is only used to denote midnight at the end of a calendar day. In EnergyPlus output, "00:24:00" with a time interval being 15 mins represents a time period from "00:23:45" to "00:24:00", and similarly "00:15:00" represents a time period from "00:24:00" to "00:15:00" of the next day. This means that if current day is Friday, day of week rule applied in schedule time period "00:23:45" to "00:24:00" (presented as "00:24:00" in the output) is also Friday, but not Saturday. However, if you try to get the day of week of time "00:24:00" in R, you will get Saturday, but not Friday. This introduces inconsistency and may cause problems when doing data analysis considering day of week value.

With `wide` equals `TRUE`, `$report_data()` will format the simulation output in the same way as standard EnergyPlus csv output file. Sometimes this can be useful as there may be existing tools/workflows that depend on this format. When both `wide` and `all` are `TRUE`, columns of runperiod environment names and date time components are also returned, including: `environment_period_index`, `environment_name`, `simulation_days`, `datetime`, `month`, `day`, `hour`, `minute`, `day_type`.

For convenience, input character arguments matching in `$report_data()` are **case-insensitive**.

Returns: A `data.table::data.table()`.

Examples:

```

\dontrun{
# read all report data
sql$report_data()

# specify output variables using report data dictionary
dict <- sql$report_data_dict()
sql$report_data(dict[units == "C"])

# specify output variables using 'key_value' and 'name'
sql$report_data("environment", "site outdoor air drybulb temperature")

# explicitly specify year value and time zone
sql$report_data(dict[1], year = 2020, tz = "Etc/GMT+8")

# explicitly specify case name
sql$report_data(dict[1], case = "example")

# get all possible columns
sql$report_data(dict[1], all = TRUE)

# return in a format that is similar as EnergyPlus CSV output
sql$report_data(dict[1], wide = TRUE)

# return in a format that is similar as EnergyPlus CSV output with
# extra columns
sql$report_data(dict[1], wide = TRUE, all = TRUE)

# only get data at the working hour on the first Monday
sql$report_data(dict[1], hour = 8:18, day_type = "monday", simulation_days = 1:7)

# only get specified run period data
sql$read_table("EnvironmentPeriods") # possible environment name
sql$report_data(dict[1], environment_name = "San Francisco Intl Ap CA USA TMY3 WMO#=724940")
# can also be done using 'environment_period_index' column
sql$report_data(dict[1], all = TRUE)[environment_period_index == 3L]
}

```

Method `tabular_data()`: Read tabular data

Usage:

```

EplusSql$tabular_data(
  report_name = NULL,
  report_for = NULL,
  table_name = NULL,
  column_name = NULL,
  row_name = NULL,
  case = "auto",

```

```

    wide = FALSE,
    string_value = !wide
  )

```

Arguments:

`report_name`, `report_for`, `table_name`, `column_name`, `row_name` Each is a character vector for subsetting when querying the SQL database. For the meaning of each argument, please see the description above.

`case` A single string used to add a character column `case` in the returned results to indicate the case of this simulation. If `NULL`, no column is added. If "auto", the name of the IDF file without extension is used. Default: "auto".

`wide` If `TRUE`, each table will be converted into the similar format as it is shown in EnergyPlus HTML output file. Default: `FALSE`.

`string_value` Only applicable when `wide` is `TRUE`. If `string_value` is `FALSE`, instead of keeping all values as characters, values in possible numeric columns are converted into numbers. Default: the opposite of `wide`. Possible numeric columns indicate column that:

- columns that have associated units
- columns that contents numbers

Details: `$tabular_data()` extracts the tabular data in a `data.table::data.table()` using `report`, `table`, `column` and `row` name specifications. The returned `data.table::data.table()` has 9 columns:

- `case`: Simulation case specified using `case` argument
- `index`: Tabular data index
- `report_name`: The name of the report that the record belongs to
- `report_for`: The For text that is associated with the record
- `table_name`: The name of the table that the record belongs to
- `column_name`: The name of the column that the record belongs to
- `row_name`: The name of the row that the record belongs to
- `units`: The units of the record
- `value`: The value of the record **in string format** by default.

For convenience, input character arguments matching in `$tabular_data()` are **case-insensitive**.

Returns: A `data.table::data.table()` with 9 columns (when `wide` is `FALSE`) or a named list of `data.table::data.table()`s where the names are the combination of `report_name`, `report_for` and `table_name`.

Examples:

```

\dontrun{
# read all tabular data
sql$tabular_data()

# explicitly specify data you want
str(sql$tabular_data(
  report_name = "AnnualBuildingUtilityPerformanceSummary",
  table_name = "Site and Source Energy",
  column_name = "Total Energy",
  row_name = "Total Site Energy"

```

```

))

# get tabular data in wide format and coerce numeric values
str(sql$tabular_data(
  report_name = "AnnualBuildingUtilityPerformanceSummary",
  table_name = "Site and Source Energy",
  column_name = "Total Energy",
  row_name = "Total Site Energy",
  wide = TRUE, string_value = FALSE
))
}

```

Method print(): Print EplusSql object

Usage:

```
EplusSql#print()
```

Details: \$print() shows the core information of this EplusSql object, including the path of the EnergyPlus SQLite file, last modified time of the SQLite file and the path of the IDF file with the same name in the same folder.

Returns: The EplusSql object itself, invisibly.

Examples:

```

\dontrun{
sql#print()
}

```

eplus_job

Create an EnergyPlus Simulation Job

Description

eplus_job() takes an IDF and EPW as input, and returns an EplusJob object for running EnergyPlus simulation and collecting outputs. For more details, please see [EplusJob](#).

Usage

```
eplus_job(idf, epw)
```

Arguments

`idf` A path to a local EnergyPlus IDF file or an `Idf` object.

`epw` A path to a local EnergyPlus EPW file or an `Epw` object. `epw` can also be `NULL` which will force design-day-only simulation when `$run()` method is called. Note this needs at least one `Sizing:DesignDay` object exists in the `Idf`.

Value

An `EplusJob` object.

Author(s)

Hongyuan Jia

See Also

[param_job\(\)](#) for creating an EnergyPlus parametric job.

Examples

```
## Not run:
if (is_avail_eplus(8.8)) {
  idf_name <- "1ZoneUncontrolled.idf"
  epw_name <- "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"

  idf_path <- file.path(eplus_config(8.8)$dir, "ExampleFiles", idf_name)
  epw_path <- file.path(eplus_config(8.8)$dir, "WeatherData", epw_name)

  # create from local files
  eplus_job(idf_path, epw_path)

  # create from an Idf and an Epw object
  eplus_job(read_idf(idf_path), read_epw(epw_path))
}

## End(Not run)
```

eplus_sql

Read an Energy SQLite Output File

Description

`eplus_sql()` takes an EnergyPlus SQLite output file as input, and returns an `EplusSQL` object for collecting simulation outputs. For more details, please see [EplusSql](#).

Usage

```
eplus_sql(sql)
```

Arguments

`sql` A path to a local EnergyPlus SQLite output file.

Value

An `EplusSql` object.

Author(s)

Hongyuan Jia

Examples

```
## Not run:
if (is_avail_eplus(8.8)) {
  idf_name <- "1ZoneUncontrolled.idf"
  epw_name <- "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"

  idf_path <- file.path(eplus_config(8.8)$dir, "ExampleFiles", idf_name)
  epw_path <- file.path(eplus_config(8.8)$dir, "WeatherData", epw_name)

  # copy to tempdir and run the model
  idf <- read_idf(idf_path)
  idf$run(epw_path, tempdir(), echo = FALSE)

  # create from local file
  sql <- eplus_sql(file.path(tempdir(), "1ZoneUncontrolled.sql"))
}

## End(Not run)
```

Epw

Read, and modify an EnergyPlus Weather File (EPW)

Description

Reading an EPW file starts with function `read_epw()`, which parses an EPW file and returns an `Epw` object. The parsing process is basically as [EnergyPlus/WeatherManager.cc] in EnergyPlus, with some simplifications.

Details

An EPW file can be divided into two parts, headers and weather data. The first eight lines of a standard EPW file are normally headers which contains data of location, design conditions, typical/extreme periods, ground temperatures, holidays/daylight savings, data periods and other comments. `Epw` class provides methods to directly extract those data. For details on the data structure of EPW file, please see "Chapter 2 - Weather Converter Program" in EnergyPlus "Auxiliary Programs" documentation. An online version can be found [here](#).

There are about 35 variables in the core weather data. However, not all of them are used by EnergyPlus. Actually, despite of date and time columns, only 13 columns are used:

1. dry bulb temperature
2. dew point temperature
3. relative humidity
4. atmospheric pressure
5. horizontal infrared radiation intensity from sky
6. direct normal radiation
7. diffuse horizontal radiation
8. wind direction
9. wind speed
10. present weather observation
11. present weather codes
12. snow depth
13. liquid precipitation depth

Note the hour column in the core weather data corresponds to the period from **(Hour-1)th** to **(Hour)th**. For instance, if the number of interval per hour is 1, hour of 1 on a certain day corresponds to the period between 00:00:01 to 01:00:00, Hour of 2 corresponds to the period between 01:00:01 to 02:00:00, and etc. Currently, in EnergyPlus the minute column is **not used** to determine currently sub-hour time. For instance, if the number of interval per hour is 2, there is no difference between two rows with following time columns (a) Hour 1, Minute 0; Hour 1, Minute 30 and (b) Hour 1, Minute 30; Hour 1, Minute 60. Only the number of rows count. When EnergyPlus reads the EPW file, both (a) and (b) represent the same time period: 00:00:00 - 00:30:00 and 00:30:00 - 01:00:00. Missing data on the weather file used can be summarized in the eplusout.err file, if DisplayWeatherMissingDataWarnings is turned on in Output:Diagnostics object. In EnergyPlus, missing data is shown only for fields that EnergyPlus will use. EnergyPlus will fill some missing data automatically during simulation. Likewise out of range values are counted for each occurrence and summarized. However, note that the out of range values will **not be changed** by EnergyPlus and could affect your simulation.

Epw class provides methods to easily extract and inspect those abnormal (missing and out of range) weather data and also to know what kind of actions that EnergyPlus will perform on those data.

EnergyPlus energy model calibration often uses actual measured weather data. In order to streamline the error-prone process of creating custom EPW file, Epw provides methods to direction add, replace the core weather data.

Methods

Public methods:

- [Epw\\$new\(\)](#)
- [Epw\\$path\(\)](#)
- [Epw\\$location\(\)](#)
- [Epw\\$design_condition\(\)](#)

- `Epw$typical_extreme_period()`
- `Epw$ground_temperature()`
- `Epw$holiday()`
- `Epw$comment1()`
- `Epw$comment2()`
- `Epw$num_period()`
- `Epw$interval()`
- `Epw$period()`
- `Epw$missing_code()`
- `Epw$initial_missing_value()`
- `Epw$range_exist()`
- `Epw$range_valid()`
- `Epw$fill_action()`
- `Epw$data()`
- `Epw$abnormal_data()`
- `Epw$redundant_data()`
- `Epw$make_na()`
- `Epw$fill_abnormal()`
- `Epw$add_unit()`
- `Epw$drop_unit()`
- `Epw$purge()`
- `Epw$add()`
- `Epw$set()`
- `Epw$del()`
- `Epw$is_unsaved()`
- `Epw$save()`
- `Epw$print()`
- `Epw$clone()`

Method `new()`: Create an Epw object

Usage:

```
Epw$new(path, warning = FALSE)
```

Arguments:

`path` Either a path, a connection, or literal data (either a single string or a raw vector) to an EnergyPlus Weather File (EPW). If a file path, that file usually has an extension `.epw`.

`warning` If TRUE, warnings are given if any missing data, out-of-range data are found. Default: TRUE.

Details: It takes an EnergyPlus Weather File (EPW) as input and returns an EPW object.

Returns: An Epw object.

Examples:

```

\dontrun{
# read an EPW file from EnergyPlus website
path_base <- "https://energyplus.net/weather-download"
path_region <- "north_and_central_america_wmo_region_4/USA/CA"
path_file <- "USA_CA_San.Francisco.Intl.AP.724940_TMY3/USA_CA_San.Francisco.Intl.AP.724940_TMY3.e
path_epw <- file.path(path_base, path_region, path_file)
epw <- read_epw(path_epw)

# read an EPW file distributed with EnergyPlus
if (is_avail_eplus(8.8)) {
  path_epw <- file.path(
    eplus_config(8.8)$dir,
    "WeatherData",
    "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"
  )
  epw <- read_epw(path_epw)
}
}

```

Method `path()`: Get the file path of current Epw

Usage:

```
Epw$path()
```

Details: `$path()` returns the full path of current Epw or NULL if the Epw object is created using a character vector and not saved locally.

Returns: NULL or a single string.

Examples:

```

\dontrun{
# get path
epw$path()
}

```

Method `location()`: Get and modify LOCATION header

Usage:

```

Epw$location(
  city,
  state_province,
  country,
  data_source,
  wmo_number,
  latitude,
  longitude,
  time_zone,
  elevation
)

```

Arguments:

`city` A string of city name recorded in the LOCATION header.

`state_province` A string of state or province name recorded in the LOCATION header.

`country` A string of country name recorded in the LOCATION header.

`data_source` A string of data source recorded in the LOCATION header.

`wmo_number` A string of WMO (World Meteorological Organization) number recorded in the LOCATION header.

`latitude` A number of latitude recorded in the LOCATION header. North latitude is positive and south latitude is negative. Should in range [-90, +90].

`longitude` A number of longitude recorded in the LOCATION header. East longitude is positive and west longitude is negative. Should in range [-180, +180].

`time_zone` A number of time zone recorded in the LOCATION header. Usually presented as the offset hours from UTC time. Should in range [-12, +14].

`elevation` A number of elevation recorded in the LOCATION header. Should in range [-1000, 9999.9).

Details: `$location()` takes new values for LOCATION header fields and returns the parsed values of LOCATION header in a list format. If no input is given, current LOCATION header value is returned.

Returns: A named list of 9 elements.

Examples:

```
\dontrun{
epw$location()

# modify location data
epw$location(city = "MyCity")
}
```

Method `design_condition()`: Get DESIGN CONDITION header

Usage:

```
Epw$design_condition()
```

Details: `$design_condition()` returns the parsed values of DESIGN CONDITION header in a list format with 4 elements:

- `source`: A string of source field
- `heating`: A list, usually of length 16, of the heating design conditions
- `cooling`: A list, usually of length 32, of the cooling design conditions
- `extreme`: A list, usually of length 16, of the extreme design conditions

For the meaning of each element, please see ASHRAE Handbook of Fundamentals.

Returns: A named list of 4 elements.

Examples:

```
\dontrun{
epw$design_condition()
}
```

Method `typical_extreme_period()`: Get TYPICAL/EXTREME header

Usage:

```
Epw$typical_extreme_period()
```

Details: `$typical_extreme_period()` returns the parsed values of TYPICAL/EXTREME PERIOD header in a [data.table](#) format with 6 columns:

- `index`: Integer type. The index of typical or extreme period record
- `name`: Character type. The name of typical or extreme period record
- `type`: Character type. The type of period. Possible value: `typical` and `extreme`
- `start_day`: Date type with customized formatting. The start day of the period
- `end_day`: Date type with customized formatting. The end day of the period

Returns: A `data.table::data.table()` with 6 columns.

Examples:

```
\dontrun{
epw$typical_extreme_period()
}
```

Method `ground_temperature()`: Get GROUND TEMPERATURE header

Usage:

```
Epw$ground_temperature()
```

Details: `$ground_temperature()` returns the parsed values of GROUND TEMPERATURE header in a [data.table](#) format with 7 columns:

- `index`: Integer type. The index of ground temperature record
- `depth`: Numeric type. The depth of the ground temperature is measured
- `month`: Integer type. The month when the ground temperature is measured
- `soil_conductivity`: Numeric type. The soil conductivity at measured depth
- `soil_density`: Numeric type. The soil density at measured depth
- `soil_specific_heat`: Numeric type. The soil specific heat at measured depth
- `temperature`: Numeric type. The measured group temperature

Returns: A `data.table::data.table()` with 7 columns.

Examples:

```
\dontrun{
epw$ground_temperature()
}
```

Method `holiday()`: Get and modify HOLIDAYS/DAYLIGHT SAVINGS header

Usage:

```
Epw$holiday(leapyear, dst, holiday)
```

Arguments:

`leapyear` Either TRUE or FALSE.

`dst` A length 2 EPW date specifications identifying the start and end of daylight saving time.
For example, `c(3.10, 10.3)`.

holiday a list or a data.frame containing two elements (columns) name and day where name are the holiday names and day are valid EPW date specifications. For example:

```
list(name = c("New Year's Day", "Christmas Day"), day = c("1.1", "25 Dec"))
```

Details: \$holiday() takes new value for leap year indicator, daylight saving time and holiday specifications, set these new values and returns the parsed values of HOLIDAYS/DAYLIGHT SAVINGS header. If no input is given, current values of HOLIDAYS/DAYLIGHT SAVINGS header is returned. It returns a list of 3 elements:

- leapyear: A single logical vector. TRUE means that the weather data contains leap year data
- dst: A Date vector contains the start and end day of daylight saving time
- holiday: A [data.table](#) contains 2 columns. If no holiday specified, an empty [data.table](#)
 - name: Name of the holiday
 - day: Date of the holiday

Validation process below is performed when changing the leapyear indicator:

- If current record of leapyear is TRUE, but new input is FALSE, the modification is only conducted when all data periods do not cover Feb 29.
- If current record of leapyear is FALSE, but new input is TRUE, the modification is only conducted when TMY data periods do not across Feb, e.g. [01/02, 02/28], [03/01, 12/31]; for AMY data, it is always OK.

The date specifications in dst and holiday should follow the rules of "**Table 2.14: Weather File Date File Interpretation**" in "AuxiliaryPrograms" documentation. eplusr is able to handle all those kinds of formats automatically. Basically, 5 formats are allowed:

1. A single integer is interpreted as the Julian day of year. For example, 1, 2, 3 and 4 will be parsed and presented as 1st day, 2nd day, 3rd day and 4th day.
2. A single number is interpreted as Month.Day. For example, 1.2 and 5.6 will be parsed and presented as Jan 02 and May 06.
3. A string giving MonthName / DayNumber, DayNumber / MonthName, and MonthNumber / DayNumber. A year number can be also included. For example, "Jan/1", "05/Dec", "7/8", "02/10/2019", and "2019/04/05" will be parsed and presented as Jan 02, Dec 06, Jul 8, 2019-02-10 and 2019-04-15.
4. A string giving number Weekday in Month. For example, "2 Sunday in Jan" will be parsed and presented as 2th Sunday in January.
5. A string giving Last Weekday in Month. For example, "last Sunday in Dec" will be parsed and presented as Last Sunday in December.

For convenience, besides all the formats described above, dst and days in holiday also accept standard Dates input. They will be treated as the same way as No.3 format described above.

Returns: A named list of 3 elements.

Examples:

```
\dontrun{
epw$holiday()

# add daylight saving time
epw$holiday(dst = c(3.10, 11.3))
}
```

Method comment1(): Get and modify COMMENT1 header

Usage:

```
Epw$comment1(comment)
```

Arguments:

comment A string of new comments.

Details: \$comment1() takes a single string of new comments and replaces the old comment with input one. If no input is given, current comment is returned.

Returns: A single string.

Examples:

```
\dontrun{
epw$comment1()

epw$comment1("Comment1")
}
```

Method comment2(): Get and modify COMMENT2 header

Usage:

```
Epw$comment2(comment)
```

Arguments:

comment A string of new comments.

Details: \$comment2() takes a single string of new comments and replaces the old comment with input one. If no input is given, current comment is returned.

Returns: A single string.

Examples:

```
\dontrun{
epw$comment2()

epw$comment2("Comment2")
}
```

Method num_period(): Get number of data periods in DATA PERIODS header

Usage:

```
Epw$num_period()
```

Details: \$num_period() returns a single positive integer of how many data periods current Epw contains.

Returns: A single integer.

Examples:

```
\dontrun{
epw$num_period()
}
```

Method `interval()`: Get the time interval in DATA PERIODS header

Usage:

```
Epw$interval()
```

Details: `$interval()` returns a single positive integer of how many records of weather data exist in one hour.

Returns: A single integer.

Examples:

```
\dontrun{
epw$interval()
}
```

Method `period()`: Get and modify data period meta data in DATA PERIODS header

Usage:

```
Epw$period(period, name, start_day_of_week)
```

Arguments:

`period` A positive integer vector identifying the data period indexes.

`name` A character vector used as new names for specified data periods. Should have the same length as `index`.

`start_day_of_week` A character vector or an integer vector used as the new start days of week of specified data periods. Should have the same length as `index`.

Details: `$period()` takes a data period index, a new period name and start day of week specification, and uses that input to replace the data period's name and start day of week. If no input is given, data periods in current Epw is returned.

Returns: A [data.table](#) with 5 columns:

- `index`: Integer type. The index of data period.
- `name`: Character type. The name of data period.
- `start_day_of_week`: Integer type. The start day of week of data period.
- `start_day`: Date (EpwDate) type. The start day of data period.
- `end_day`: Date (EpwDate) type. The end day of data period.

Examples:

```
\dontrun{
# modify data period name
epw$period(1, name = "test")

# change start day of week
epw$period(1, start_day_of_week = 3)
}
```

Method `missing_code()`: Get missing code for weather data variables

Usage:

```
Epw$missing_code()
```

Details: \$missing_code() returns a list of 29 elements containing the value used as missing value identifier for all weather data.

Returns: A named list of 29 elements.

Examples:

```
\dontrun{
epw$missing_code()
}
```

Method initial_missing_value(): Get initial value for missing data of weather data variables

Usage:

```
Epw$initial_missing_value()
```

Details: \$initial_missing_value() returns a list of 16 elements containing the initial value used to replace missing values for corresponding weather data.

Returns: A named list of 16 elements.

Examples:

```
\dontrun{
epw$initial_missing_value()
}
```

Method range_exist(): Get value ranges for existing values of weather data variables

Usage:

```
Epw$range_exist()
```

Details: \$range_exist() returns a list of 28 elements containing the range each numeric weather data should fall in. Any values out of this range are treated as missing.

Returns: A named list of 28 elements.

Examples:

```
\dontrun{
epw$range_exist()
}
```

Method range_valid(): Get value ranges for valid values of weather data variables

Usage:

```
Epw$range_valid()
```

Details: \$range_valid() returns a list of 28 elements containing the range each numeric weather data should fall in. Any values out of this range are treated as invalid.

Returns: A named list of 28 elements.

Examples:

```
\dontrun{
epw$range_valid()
}
```

Method fill_action(): Get fill actions for abnormal values of weather data variables

Usage:

```
Epw$fill_action(type = c("missing", "out_of_range"))
```

Arguments:

type What abnormal type of actions to return. Should be one of "missing" and "out_of_range".
Default: "missing".

Details: \$fill_action() returns a list containing actions that EnergyPlus will perform when certain abnormal data found for corresponding weather data. There are 3 types of actions in total:

- do_nothing: All abnormal values are left as they are.
- use_zero: All abnormal values are reset to zeros.
- use_previous: The first abnormal values of variables will be set to the initial missing values. All after are set to previous valid one.

Returns: A named list.

Examples:

```
\dontrun{
epw$fill_action("missing")

epw$fill_action("out_of_range")
}
```

Method data(): Get weather data

Usage:

```
Epw$data(
  period = 1L,
  start_year = NULL,
  align_wday = TRUE,
  tz = "UTC",
  update = FALSE
)
```

Arguments:

period A single positive integer identifying the data period index. Data periods information can be obtained using `$period()` described above.

start_year A positive integer identifying the year of first date time in specified data period. If NULL, the values in the year column are used as years of datet ime column. Default: NULL.

align_wday Only applicable when start_year is NULL. If TRUE, a year value is automatically calculated for specified data period that compliance with the start day of week value specified in DATA PERIODS header.

tz A valid time zone to be assigned to the datet ime column. All valid time zone names can be obtained using `OlsonNames()`. Default: "UTC".

update If TRUE, the year column are updated according to the newly created datet ime column using start_year. If FALSE, original year data in the Epw object is kept. Default: FALSE.

Details: `$data()` returns weather data of specific data period.

Usually, EPW file downloaded from [EnergyPlus website](#) contains TMY weather data. As years of weather data is not consecutive, it may be more convenient to align the year values to be consecutive, which will makes it possible to direct analyze and plot weather data. The `start_year` argument in `$data()` method can help to achieve this. However, randomly setting the year may result in a date time series that does not have the same start day of week as specified in the DATA PERIODS header. `eplusr` provides a simple solution for this. By setting `year` to `NULL` and `align_wday` to `TRUE`, `eplusr` will calculate a year value (from current year backwards) for each data period that compliance with the start day of week restriction.

Note that if current data period contains AMY data and `start_year` is given, a warning is given because the actual year values will be overwritten by input `start_year`. An error is given if:

- Using input `start_year` introduces invalid date time. This may happen when weather data contains leap year but input `start_year` is not a leap year.
- Applying specified time zone specified using `tz` introduces invalid date time.

Returns: A `data.table::data.table()` of 36 columns.

Examples:

```
\dontrun{
# get weather data
str(epw$data())

# get weather data but change the year to 2018
# the year column is not changed by default, only the returned datetime column
head(epw$data(start_year = 2018)$datetime)
str(epw$data(start_year = 2018)$year)
# you can update the year column too
head(epw$data(start_year = 2018, update = TRUE)$year)

# change the time zone of datetime column in the returned weather data
attributes(epw$data()$datetime)
attributes(epw$data(tz = "Etc/GMT+8")$datetime)
}
```

Method `abnormal_data()`: Get abnormal weather data

Usage:

```
Epw$abnormal_data(
  period = 1L,
  cols = NULL,
  keep_all = TRUE,
  type = c("both", "missing", "out_of_range")
)
```

Arguments:

`period` A single positive integer identifying the data period index. Data periods information can be obtained using `$period()` described above.

`cols` A character vector identifying what data columns, i.e. all columns except `datetime`, `year`, `month`, `day`, `hour` and `minute`, to search abnormal values. If `NULL`, all data columns are used. Default: `NULL`.

`keep_all` If TRUE, all columns are returned. If FALSE, only line, datetime, year, month, day, hour and minute, together with columns specified in `cols` are returned. Default: TRUE

`type` What abnormal type of data to return. Should be one of "all", "missing" and "out_of_range". Default: "all".

Details: `$abnormal_data()` returns abnormal data of specific data period. Basically, there are 2 types of abnormal data in Epw, i.e. missing values and out-of-range values. Sometimes, it may be useful to extract and inspect those data especially when inserting measured weather data. `$abnormal_data()` does this.

In the returned `data.table::data.table()`, a column named `line` is created indicating the line numbers where abnormal data occur in the actual EPW file.

Returns: A `data.table::data.table()`.

Examples:

```
\dontrun{
epw$abnormal_data()

# only check if there are any abnormal values in air temperature and
# liquid precipitation rate
epw$abnormal_data(cols = c("dry_bulb_temperature", "liquid_precip_rate"))

# save as above, but only return date time columns plus those 2 columns
epw$abnormal_data(cols = c("dry_bulb_temperature", "liquid_precip_rate"),
  keep_all = FALSE
)

# same as above, but only check for missing values
epw$abnormal_data(cols = c("dry_bulb_temperature", "liquid_precip_rate"),
  type = "missing"
)

# same as above, but only check for out-of-range values
epw$abnormal_data(cols = c("dry_bulb_temperature", "liquid_precip_rate"),
  type = "out_of_range"
)
}
```

Method `redundant_data()`: Get redundant weather data

Usage:

```
Epw$redundant_data()
```

Details: `$redundant_data()` returns weather data in Epw object that do not belong to any data period. This data can be further removed using `$purge()` method described below.

In the returned `data.table::data.table()`, a column named `line` is created indicating the line numbers where redundant data occur in the actual EPW file.

Returns: A `data.table::data.table()` of 37 columns.

Examples:

```
\dontrun{
epw$redundant_data()
}
```

Method `make_na()`: Convert abnormal data into NAs

Usage:

```
Epw$make_na(period = NULL, missing = FALSE, out_of_range = FALSE)
```

Arguments:

`period` A positive integer vector identifying the data period indexes. Data periods information can be obtained using `$period()` described above. If `NULL`, all data periods are included.
Default: `NULL`.

`missing` If `TRUE`, missing values are included. Default: `FALSE`.

`out_of_range` If `TRUE`, out-of-range values are included. Default: `FALSE`.

Details: `$make_na()` converts specified abnormal data into NAs in specified data period. This makes it easier to find abnormal data directly using `is.na()` instead of using `$missing_code()`. `$make_na()` and `$fill_abnormal()` are reversible, i.e. `$make_na()` can be used to counteract the effects introduced by `$make_na()`, and vice versa.

Note that `$make_na` modify the weather data in-place, meaning that the returned data from `$data()` and `$abnormal_data()` may be different after calling `$make_na()`.

Returns: The modified Epw object itself, invisibly.

Examples:

```
\dontrun{
# turn all missing values into NAs
summary(epw$data()$liquid_precip_rate)
epw$make_na(missing = TRUE)
summary(epw$data()$liquid_precip_rate)
}
```

Method `fill_abnormal()`: Fill abnormal data using prescribed pattern

Usage:

```
Epw$fill_abnormal(
  period = NULL,
  missing = FALSE,
  out_of_range = FALSE,
  special = FALSE
)
```

Arguments:

`period` A positive integer vector identifying the data period indexes. Data periods information can be obtained using `$period()` described above. If `NULL`, all data periods are included.
Default: `NULL`.

`missing` If `TRUE`, missing values are included. Default: `FALSE`.

`out_of_range` If `TRUE`, out-of-range values are included. Default: `FALSE`.

`special` If TRUE, abnormal data are filled using corresponding actions listed `$fill_action()`.
If FALSE, all abnormal data are fill with missing code described in `$missing_code()`.

Details: `$fill_abnormal()` fills specified abnormal data using corresponding actions listed in `$fill_action()`. For what kinds of actions to be performed, please see `$fill_action()` method described above. Note that only if `special` is TRUE, special actions listed in `$fill_action()` is performed. If `special` is FALSE, all abnormal data, including both missing values and out-of-range values, are filled with corresponding missing codes.

`$make_na()` and `$fill_abnormal()` are reversible, i.e. `$make_na()` can be used to counteract the effects introduced by `$fill_abnormal()`, and vice a versa.

Note that `$fill_abnormal` modify the weather data in-place, meaning that the returned data from `$data()` and `$abnormal_data()` may be different after calling `$fill_abnormal()`.

Returns: The modified Epw object itself, invisibly.

Examples:

```
\dontrun{
# turn all missing values into NAs
summary(epw$data()$liquid_precip_rate)
epw$fill_abnormal(missing = TRUE)
summary(epw$data()$liquid_precip_rate)
}
```

Method `add_unit()`: Add units to weather data variables

Usage:

```
Epw$add_unit()
```

Details: `$add_unit()` assigns units to numeric weather data using `units::set_units()` if applicable.

`$add_unit()` and `$drop_unit()` are reversible, i.e. `$add_unit()` can be used to counteract the effects introduced by `$drop_unit()`, and vice a versa.

Note that `$add_unit` modify the weather data in-place, meaning that the returned data from `$data()` and `$abnormal_data()` may be different after calling `$add_unit()`.

Returns: The modified Epw object itself, invisibly.

Examples:

```
\dontrun{
# get weather data with units
epw$add_unit()
head(epw$data())

# with units specified, you can easily perform unit conversion using units
# package
t_dry_bulb <- epw$data()$dry_bulb_temperature
units(t_dry_bulb) <- with(units::ud_units, "kelvin")

head(t_dry_bulb)
}
```

Method `drop_unit()`: Remove units in weather data variables

Usage:

```
Epw$drop_unit()
```

Details: `$drop_unit()` removes all units of numeric weather data.

`$add_unit()` and `$drop_unit()` are reversible, i.e. `$add_unit()` can be used to counteract the effects introduced by `$drop_unit()`, and vice a versa.

Note that `$add_unit` modify the weather data in-place, meaning that the returned data from `$data()` and `$abnormal_data()` may be different after calling `$add_unit()`.

Returns: The modified Epw object itself, invisibly.

Examples:

```
\dontrun{
epw$drop_unit()
epw$data()
}
```

Method `purge()`: Delete redundant weather data observations

Usage:

```
Epw$purge()
```

Details: `$purge()` deletes weather data in Epw object that do not belong to any data period.

Returns: The modified Epw object itself, invisibly.

Examples:

```
\dontrun{
epw$purge()
}
```

Method `add()`: Add a data period

Usage:

```
Epw$add(
  data,
  realyear = FALSE,
  name = NULL,
  start_day_of_week = NULL,
  after = 0L,
  warning = TRUE
)
```

Arguments:

`data` A `data.table::data.table()` of new weather data to add or set. Validation is performed according to rules described above.

`realyear` Whether input data is AMY data. Default: FALSE.

`name` A new string used as name of added or set data period. Should not be the same as existing data period names. If NULL, it is generated automatically in format `Data`, `Data_1` and etc., based on existing data period names. Default: NULL

`start_day_of_week` A single integer or character specifying start day of week of input data period. If NULL, Sunday is used for TMY data and the actual start day of week is used for AMY data. Default: NULL.

`after` A single integer identifying the index of data period where input new data period to be inserted after. IF 0, input new data period will be the first data period. Default: 0.

`warning` If TRUE, warnings are given if any missing data, out-of-range data are found. Default: TRUE.

Details: `$add()` adds a new data period into current Epw object at specified position.

The validity of input data is checked before adding according to rules following:

- Column `datetime` exists and has type of `POSIXct`. Note that time zone of input date time will be reset to UTC.
- It assumes that input data is already sorted, i.e. no further sorting is made during validation. This is because when input data is TMY data, there is no way to properly sort input data rows only using `datetime` column.
- Number of data records per hour should be consistent across input data.
- Input number of data records per hour should be the same as existing data periods.
- The date time of input data should not overlap with existing data periods.
- Input data should have all 29 weather data columns with right types. The year, month, day, and minute column are not compulsory. They will be created according to values in the `datetime` column. Existing values will be overwritten.

Returns: The modified Epw object itself, invisibly.

Examples:

```
\dontrun{
# will fail since date time in input data has already been covered by
# existing data period
epw$add(epw$data())
}
```

Method `set()`: Replace a data period

Usage:

```
Epw$set(
  data,
  realyear = FALSE,
  name = NULL,
  start_day_of_week = NULL,
  period = 1L,
  warning = TRUE
)
```

Arguments:

`data` A `data.table::data.table()` of new weather data to add or set. Validation is performed according to rules described above.

`realyear` Whether input data is AMY data. Default: FALSE.

`name` A new string used as name of added or set data period. Should not be the same as existing data period names. If NULL, it is generated automatically in format `Data`, `Data_1` and etc., based on existing data period names. Default: NULL

`start_day_of_week` A single integer or character specifying start day of week of input data period. If NULL, Sunday is used for TMY data and the actual start day of week is used for AMY data. Default: NULL.

`period` A single integer identifying the index of data period to set.

`warning` If TRUE, warnings are given if any missing data, out-of-range data are found. Default: TRUE.

Details: `$set()` replaces existing data period using input new weather data.

The validity of input data is checked before replacing according to rules following:

- Column `datetime` exists and has type of POSIXct. Note that time zone of input date time will be reset to UTC.
- It assumes that input data is already sorted, i.e. no further sorting is made during validation. This is because when input data is TMY data, there is no way to properly sort input data rows only using `datetime` column.
- Number of data records per hour should be consistent across input data.
- Input number of data records per hour should be the same as existing data periods.
- The date time of input data should not overlap with existing data periods.
- Input data should have all 29 weather data columns with right types. The year, month, day, and minute column are not compulsory. They will be created according to values in the `datetime` column. Existing values will be overwritten.

Returns: The modified Epw object itself, invisibly.

Examples:

```
\dontrun{
# change the weather data
epw$set(epw$data(), warning = FALSE)
}
```

Method `del()`: Delete a data period

Usage:

```
Epw$del(period)
```

Arguments:

`period` A single integer identifying the index of data period to set.

Details: `$del()` removes a specified data period. Note that an error will be given if current Epw only contains one data period.

Returns: The modified Epw object itself, invisibly.

Method `is_unsaved()`: Check if there are unsaved changes in current Epw

Usage:

```
Epw$is_unsaved()
```

Details: `$is_unsaved()` returns TRUE if there are modifications on the Epw object since it was read or since last time it was saved, and returns FALSE otherwise.

Returns: A single logical value of TRUE or FALSE.

Examples:

```
\dontrun{
epw$save()
}
```

Method save(): Save Epw object as an EPW file

Usage:

```
Epw$save(path = NULL, overwrite = FALSE, purge = FALSE)
```

Arguments:

path A path where to save the weather file. If NULL, the path of the weather file itself is used.

Default: NULL.

overwrite Whether to overwrite the file if it already exists. Default is FALSE.

purge Whether to remove redundant data when saving. Default: FALSE.

Details: \$save() saves current Epw to an EPW file. Note that if missing values and out-of-range values are converted to NAs using `$make_na()`, they will be filled with corresponding missing codes during saving.

Returns: A length-one character vector, invisibly.

Examples:

```
\dontrun{
# save the weather file
epw$save(file.path(tempdir(), "weather.epw"), overwrite = TRUE)
}
```

Method print(): Print Idf object

Usage:

```
Epw$print()
```

Details: \$print() prints the Epw object, including location, elevation, data source, WMO station, leap year indicator, interval and data periods.

Returns: The Epw object itself, invisibly.

Examples:

```
\dontrun{
epw$print()
}
```

Method clone(): The objects of this class are cloneable with this method.

Usage:

```
Epw$clone(deep = TRUE)
```

Arguments:

deep Whether to make a deep clone.

format.IddObject *Format an IddObject*

Description

Format an [IddObject](#) into a string of an empty object of current class. It is formatted exactly the same as in IDF Editor.

Usage

```

## S3 method for class 'IddObject'
format(x, comment = NULL, leading = 4L, sep_at = 29L, all = FALSE, ...)

```

Arguments

x	An IddObject object.
comment	A character vector to be used as comments of returned string format object. If NULL, no comments are inserted. Default: NULL.
leading	Leading spaces added to each field. Default: 4.
sep_at	The character width to separate value string and field string. Default: 29 which is the same as IDF Editor.
all	If TRUE, all fields in current class are returned, otherwise only minimum fields are returned.
...	Further arguments passed to or from other methods.

Value

A single length character vector.

Examples

```
## Not run:
cat(format(use_idd(8.8, download = "auto")$Material, leading = 0))

## End(Not run)
```

format.Idf

*Format an Idf Object***Description**

Format an [Idf](#) object.

Usage

```
## S3 method for class 'Idf'
format(
  x,
  comment = TRUE,
  header = TRUE,
  format = eplusr_option("save_format"),
  leading = 4L,
  sep_at = 29L,
  ...
)
```

Arguments

x	An Idf object.
comment	If FALSE, all comments will not be included. Default: TRUE.
header	If FALSE, the header will not be included. Default: TRUE.
format	Specific format used when formatting. For details, please see <code>\$save()</code> . Default: <code>eplusr_option("save_format")</code>
leading	Leading spaces added to each field. Default: 4L.
sep_at	The character width to separate value string and field string. Default: 29L which is the same as IDF Editor.
...	Further arguments passed to or from other methods.

Value

A single length string.

Author(s)

Hongyuan Jia

Examples

```
## Not run:
idf_path <- system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr")
cat(format(read_idf(idf_path, use_idd(8.8, "auto")), leading = 0))

## End(Not run)
```

format.IdfObject	<i>Format an IdfObject</i>
------------------	----------------------------

Description

Format an [IdfObject](#) into a character vector in the same way as in IDF Editor.

Usage

```
## S3 method for class 'IdfObject'
format(x, comment = TRUE, leading = 4L, sep_at = 29L, all = FALSE, ...)
```

Arguments

x	An IdfObject object.
comment	If FALSE, all comments will not be included. Default: TRUE.
leading	Leading spaces added to each field. Default: 4L.
sep_at	The character width to separate value string and field string. Default: 29L which is the same as IDF Editor.
all	If TRUE, values of all possible fields in current class the IdfObject belongs to are returned. Default: FALSE
...	Further arguments passed to or from other methods.

Value

A character vector.

Examples

```
## Not run:
idf <- read_idf(system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr"),
  idd = use_idd(8.8, download = "auto"))

# get the IdfObject of material named "C5 - 4 IN HW CONCRETE"
mat <- idf$Material[["C5 - 4 IN HW CONCRETE"]]

cat(format(mat, leading = 0, sep_at = 10))

## End(Not run)
```

group_job

*Create An EnergyPlus Parametric Simulation Job***Description**

group_job() takes IDFs and EPWs as input and returns a EplusGroupJob. For details on EplusGroupJob, please see [EplusGroupJob](#) class.

Usage

```
group_job(idfs, epws)
```

Arguments

idfs	Paths to EnergyPlus IDF files or a list of IDF files and Idf objects.
epws	Paths to EnergyPlus EPW files or a list of EPW files and Epw objects. Each element in the list can be NULL, which will force design-day-only simulation when \$run() method is called. Note this needs at least one Sizing:DesignDay object exists in that Idf . If epws is NULL, design-day-only simulation will be conducted for all input models.

Value

A EplusGroupJob object.

Author(s)

Hongyuan Jia

See Also

[eplus_job\(\)](#) for creating an EnergyPlus single simulation job.

Examples

```
## Not run:
if (is_avail_eplus(8.8)) {
  dir <- eplus_config(8.8)$dir
  path_idfs <- list.files(file.path(dir, "ExampleFiles"), "\\*.idf",
    full.names = TRUE)[1:5]
  path_epws <- list.files(file.path(dir, "WeatherData"), "\\*.epw",
    full.names = TRUE)[1:5]

  # create from local files
  group <- group_job(path_idfs, path_epws)

  # create from Idfs and Epws object
  group_job(lapply(path_idfs, read_idf), lapply(path_epws, read_epw))
}
```

```
## End(Not run)
```

Idd

Parse, Query and Modify EnergyPlus Input Data Dictionary (IDD)

Description

eplusr provides parsing of and programmatic access to EnergyPlus Input Data Dictionary (IDD) files, and objects. It contains all data needed to parse EnergyPlus models. Idd class provides parsing and printing while [IddObject](#) provides detailed information of certain class.

Overview

EnergyPlus operates off of text input files written in its own Input Data File (IDF) format. IDF files are similar to XML files in that they are intended to conform to a data schema written using similar syntax. For XML, the schema format is XSD; for IDF, the schema format is IDD. For each release of EnergyPlus, valid IDF files are defined by the "Energy+.idd" file shipped with the release.

eplusr tries to detect all installed EnergyPlus in default installation locations when loading, i.e. C:\EnergyPlusVX-X-0 on Windows, /usr/local/EnergyPlus-X-Y-0 on Linux, and /Applications/EnergyPlus-X-Y-0 on macOS and stores all found locations internally. This data is used to locate the distributed "Energy+.idd" file of each EnergyPlus version. And also, every time an IDD file is parsed, an Idd object is created and cached in an environment.

Parsing an IDD file starts from [use_idd\(\)](#). When using [use_idd\(\)](#), eplusr will first try to find the cached Idd object of that version, if possible. If failed, and EnergyPlus of that version is available (see [avail_eplus\(\)](#)), the "Energy+.idd" distributed with EnergyPlus will be parsed and cached. So each IDD file only needs to be parsed once and can be used when parsing every IDF file of that version.

Internally, the powerful [data.table](#) package is used to speed up the whole IDD parsing process and store the results. However, it will still take about 2-3 sec per IDD. Under the hook, eplusr uses a SQL-like structure to store both IDF and IDD data in [data.table::data.table](#) format. Every IDD will be parsed and stored in four tables:

- group: contains group index and group names.
- class: contains class names and properties.
- field: contains field names and field properties.
- reference: contains cross-reference data of fields.

Methods

Public methods:

- [Idd\\$new\(\)](#)
- [Idd\\$version\(\)](#)
- [Idd\\$build\(\)](#)

- `Idd$group_name()`
- `Idd$from_group()`
- `Idd$class_name()`
- `Idd$required_class_name()`
- `Idd$unique_class_name()`
- `Idd$extensible_class_name()`
- `Idd$group_index()`
- `Idd$class_index()`
- `Idd$is_valid_group()`
- `Idd$is_valid_class()`
- `Idd$object()`
- `Idd$objects()`
- `Idd$object_relation()`
- `Idd$objects_in_relation()`
- `Idd$objects_in_group()`
- `Idd$to_table()`
- `Idd$to_string()`
- `Idd$print()`

Method `new()`: Create an Idd object

Usage:

```
Idd$new(path)
```

Arguments:

`path` Either a path, a connection, or literal data (either a single string or a raw vector) to an EnergyPlus Input Data Dictionary (IDD). If a file path, that file usually has a extension `.idd`.

Details: It takes an EnergyPlus Input Data Dictionary (IDD) as input and returns an Idd object. It is suggested to use helper `use_idd()` which supports to directly take a valid IDD version as input and search automatically the corresponding file path.

Returns: An Idd object.

Examples:

```
\dontrun{Idd$new(file.path(eplus_config(8.8)$dir, "Energy+.idd"))}
```

```
# Preferable way
idd <- use_idd(8.8, download = "auto")
}
```

Method `version()`: Get the version of current Idd

Usage:

```
Idd$version()
```

Details: `$version()` returns the version of current Idd in a `base::numeric_version()` format. This makes it easy to direction compare versions of different IdDs, e.g. `idd$version() > 8.6` or `idd1$version() > idd2$version()`.

Returns: A `base::numeric_version()` object.

Examples:

```
\dontrun{
# get version
idd$version()
}
```

Method `build()`: Get the build tag of current Idd

Usage:

```
Idd$build()
```

Details: `$build()` returns the build tag of current Idd. If no build tag is found, NA is returned.

Returns: A `base::numeric_version()` object.

Examples:

```
\dontrun{
# get build tag
idd$build()
}
```

Method `group_name()`: Get names of groups

Usage:

```
Idd$group_name()
```

Details: `$group_name()` returns names of groups current Idd contains.

Returns: A character vector.

Examples:

```
\dontrun{
# get names of all groups Idf contains
idd$group_name()
}
```

Method `from_group()`: Get the name of group that specified class belongs to

Usage:

```
Idd$from_group(class)
```

Arguments:

`class` A character vector of valid class names in current Idd.

Details: `$from_group()` returns the name of group that specified class belongs to.

Returns: A character vector.

Examples:

```
\dontrun{
idd$from_group(c("Version", "Schedule:Compact"))
}
```

Method `class_name()`: Get names of classes

Usage:

```
Idd$class_name(index = NULL, by_group = FALSE)
```

Arguments:

`index` An integer vector of class indices.

`by_group` If TRUE, a list is returned which separates class names by the group they belong to.

Default: FALSE.

Details: `$class_name()` returns names of classes current Idd contains

Returns: A character vector if `by_group` is FALSE and a list of character vectors when `by_group` is TRUE.

Examples:

```
\dontrun{
# get names of the 10th to 20th class
idd$class_name(10:20)

# get names of all classes in Idf
idd$class_name()

# get names of all classes grouped by group names in Idf
idd$class_name(by_group = TRUE)
}
```

Method `required_class_name()`: Get the names of required classes

Usage:

```
Idd$required_class_name()
```

Details: `$required_class_name()` returns the names of required classes in current Idd. "Require" means that for any Idf there should be at least one object.

Returns: A character vector.

Examples:

```
\dontrun{
idd$required_class_name()
}
```

Method `unique_class_name()`: Get the names of unique-object classes

Usage:

```
Idd$unique_class_name()
```

Details: `$unique_class_name()` returns the names of unique-object classes in current Idd. "Unique-object" means that for any Idf there should be at most one object in those classes.

Returns: A character vector.

Examples:

```

\dontrun{
idd$unique_class_name()
}

```

Method `extensible_class_name()`: Get the names of classes with extensible fields

Usage:

```
Idd$extensible_class_name()
```

Details: `$extensible_class_name()` returns the names of classes with extensible fields in current Idd. "Extensible fields" indicate fields that can be added dynamically, such like the X, Y and Z vertices of a building surface.

Returns: A character vector.

Examples:

```

\dontrun{
idd$extensible_class_name()
}

```

Method `group_index()`: Get the indices of specified groups

Usage:

```
Idd$group_index(group = NULL)
```

Arguments:

`group` A character vector of valid group names.

Details: `$group_index()` returns the indices of specified groups in current Idd. A group index is just an integer indicating its appearance order in the Idd.

Returns: An integer vector.

Examples:

```

\dontrun{
idd$group_index()
}

```

Method `class_index()`: Get the indices of specified classes

Usage:

```
Idd$class_index(class = NULL, by_group = FALSE)
```

Arguments:

`class` A character vector of valid class names.

`by_group` If TRUE, a list is returned which separates class names by the group they belong to.
Default: FALSE.

Details: `$class_index()` returns the indices of specified classes in current Idd. A class index is just an integer indicating its appearance order in the Idd.

Returns: An integer vector.

Examples:

```
\dontrun{
idd$class_index()
}
```

Method `is_valid_group()`: Check if elements in input character vector are valid group names.

Usage:

```
Idd$is_valid_group(group)
```

Arguments:

group A character vector to check.

Details: `$is_valid_group()` returns TRUEs if given character vector contains valid group names in the context of current Idd, and FALSEs otherwise.

Note that case-sensitive matching is performed, which means that "Location and Climate" is a valid group name but "location and climate" is not.

Returns: A logical vector with the same length as input character vector.

Examples:

```
\dontrun{
idd$is_valid_group(c("Schedules", "Compliance Objects"))
}
```

Method `is_valid_class()`: Check if elements in input character vector are valid class names.

Usage:

```
Idd$is_valid_class(class)
```

Arguments:

class A character vector to check.

Details: `$is_valid_class()` returns TRUEs if given character vector contains valid class names in the context of current Idd, and FALSEs otherwise.

Note that case-sensitive matching is performed, which means that "Version" is a valid class name but "version" is not.

Returns: A logical vector with the same length as input character vector.

Examples:

```
\dontrun{
idd$is_valid_class(c("Building", "ShadowCalculation"))
}
```

Method `object()`: Extract an [IddObject](#) object using class index or name.

Usage:

```
Idd$object(class)
```

Arguments:

class A single integer specifying the class index or a single string specifying the class name.

Details: \$object() returns an [IddObject](#) object specified by a class ID or name. Note that case-sensitive matching is performed, which means that "Version" is a valid class name but "version" is not.

For convenience, underscore-style names are allowed, e.g. Site_Location is equivalent to Site:Location.

Returns: An [IddObject](#) object.

Examples:

```
\dontrun{
idd$object(3)

idd$object("Building")
}
```

Method objects(): Extract multiple [IddObject](#) objects using class indices or names.

Usage:

```
Idd$objects(class)
```

Arguments:

class An integer vector specifying class indices or a character vector specifying class names.

Details: \$objects() returns a named list of [IddObject](#) objects using class indices or names. The returned list is named using class names.

Note that case-sensitive matching is performed, which means that "Version" is a valid class name but "version" is not.

For convenience, underscore-style names are allowed, e.g. Site_Location is equivalent to Site:Location.

Returns: A named list of [IddObject](#) objects.

Examples:

```
\dontrun{
idd$objects(c(3,10))

idd$objects(c("Version", "Material"))
}
```

Method object_relation(): Extract the relationship between class fields.

Usage:

```
Idd$object_relation(class, direction = c("all", "ref_to", "ref_by"))
```

Arguments:

class A single integer specifying the class index or a single string specifying the class name.

direction The relation direction to extract. Should be one of "all", "ref_to" or "ref_by".

Details: Many fields in [Idd](#) can be referred by others. For example, the Outside Layer and other fields in Construction class refer to the Name field in Material class and other material related classes. Here it means that the Outside Layer field **refers to** the Name field and the Name field is **referred by** the Outside Layer.

\$object_relation() provides a simple interface to get this kind of relation. It takes a single class index or name and also a relation direction, and returns an IddRelation object which contains data presenting such relation above. For instance, if `idd$object_relation("Construction", "ref_to")` gives results below:

```
-- Refer to Others -----
Class: <Construction>
|- Field: <02: Outside Layer>
|  v~~~~~
|  |- Class: <Material>
|  |  \- Field: <1: Name>
|  |
|  |- Class: <Material:NoMass>
|  |  \- Field: <1: Name>
|  |
|  |- Class: <Material:InfraredTransparent>
|  |  \- Field: <1: Name>
|  |
.....
```

This means that the value of field Outside Layer in class Construction can be one of values from field Name in class Material, field Name in class Material:NoMass, field Name in class Material:InfraredTransparent and etc. All those classes can be further easily extracted using \$objects_in_relation() method described below.

Returns: An IddRelation object, which is a list of 3 `data.table::data.table()`s named `ref_to` and `ref_by`. Each `data.table::data.table()` contains 12 columns.

Examples:

```
\dontrun{
# check each construction layer's possible references
idd$object_relation("Construction", "ref_to")

# check where construction being used
idd$object_relation("Construction", "ref_by")
}
```

Method `objects_in_relation()`: Extract multiple [IddObject](#) objects referencing each others.

Usage:

```
Idd$objects_in_relation(class, direction = c("ref_to", "ref_by"))
```

Arguments:

`class` A single integer specifying the class index or a single string specifying the class name.
`direction` The relation direction to extract. Should be either "ref_to" or "ref_by".

Details: `$objects_in_relation()` returns a named list of [IddObject](#) objects that have specified relationship with given class. The first element of returned list is always the specified class itself. If that class does not have specified relationship with other classes, a list that only contains specified class itself is returned.

For instance, `idd$objects_in_relation("Construction", "ref_by")` will return a named list of an [IddObject](#) object named Construction and also all other [IddObject](#) objects that can refer to field values in class Construction. Similarly, `idd$objects_in_relation("Construction", "ref_to")`

will return a named list of an [IddObject](#) object named Construction and also all other [IddObject](#) objects that Construction can refer to.

Returns: An named list of [IddObject](#) objects.

Examples:

```
\dontrun{
# get class Construction and all classes that it can refer to
idd$objects_in_relation("Construction", "ref_to")

# get class Construction and all classes that refer to it
idd$objects_in_relation("Construction", "ref_by")
}
```

Method `objects_in_group()`: Extract all [IddObject](#) objects in one group.

Usage:

```
Idd$objects_in_group(group)
```

Arguments:

group A single string of valid group name for current Idd object.

Details: `$objects_in_group()` returns a named list of all [IddObject](#) objects in specified group. The returned list is named using class names.

Returns: A named list of [IddObject](#) objects.

Examples:

```
\dontrun{
# get all classes in Schedules group
idd$objects_in_group("Schedules")
}
```

Method `to_table()`: Format Idd classes as a `data.frame`

Usage:

```
Idd$to_table(class, all = FALSE)
```

Arguments:

class A character vector of class names.

all If TRUE, all available fields defined in IDD for specified class will be returned. Default: FALSE.

Details: `$to_table()` returns a [data.table](#) that contains basic data of specified classes. The returned [data.table](#) has 3 columns:

- class: Character type. Current class name.
- index: Integer type. Field indexes.
- field: Character type. Field names.

Returns: A [data.table](#) with 3 columns.

Examples:

```

\dontrun{
# extract data of class Material
idd$to_table(class = "Material")

# extract multiple class data
idd$to_table(c("Construction", "Material"))
}

```

Method `to_string()`: Format Idf classes as a character vector

Usage:

```
idd$to_string(class, leading = 4L, sep_at = 29L, sep_each = 0L, all = FALSE)
```

Arguments:

`class` A character vector of class names.

`leading` Leading spaces added to each field. Default: 4L.

`sep_at` The character width to separate value string and field string. Default: 29L which is the same as IDF Editor.

`sep_each` A single integer of how many empty strings to insert between different classes. Default: 0.

`all` If TRUE, all available fields defined in IDD for specified class will be returned. Default: FALSE.

Details: `$to_string()` returns the text format of specified classes. The returned character vector can be pasted into an IDF file as empty objects of specified classes.

Returns: A character vector.

Examples:

```

\dontrun{
# get text format of class Material
head(idd$to_string(class = "Material"))

# get text format of multiple class
idd$to_string(c("Material", "Construction"))

# tweak output formatting
idd$to_string(c("Material", "Construction"), leading = 0, sep_at = 0, sep_each = 5)
}

```

Method `print()`: Print Idd object

Usage:

```
Idd$print()
```

Details: `$print()` prints the Idd object giving the information of version, build tag and total class numbers.

Returns: The Idd object itself, invisibly.

Examples:

```
\dontrun{
  idd$print()
}
```

IddObject

EnergyPlus IDD object

Description

IddObject is an abstraction of a single object in an [Idd](#) object. It provides more detail methods to query field properties. IddObject can only be created from the parent [Idd](#) object, using `$object()`, `$object_in_group()` and other equivalent. This is because that initialization of an IddObject needs some shared data from parent [Idd](#) object.

Details

There are lots of properties for every class and field. For details on the meaning of each property, please see the heading comments in the `Energy+.idd` file in the EnergyPlus installation path.

Methods

Public methods:

- `IddObject$new()`
- `IddObject$version()`
- `IddObject$parent()`
- `IddObject$group_name()`
- `IddObject$group_index()`
- `IddObject$class_name()`
- `IddObject$class_index()`
- `IddObject$class_format()`
- `IddObject$min_fields()`
- `IddObject$num_fields()`
- `IddObject$memo()`
- `IddObject$num_extensible()`
- `IddObject$first_extensible_index()`
- `IddObject$extensible_group_num()`
- `IddObject$add_extensible_group()`
- `IddObject$del_extensible_group()`
- `IddObject$has_name()`
- `IddObject$is_required()`
- `IddObject$is_unique()`
- `IddObject$is_extensible()`
- `IddObject$field_name()`
- `IddObject$field_index()`
- `IddObject$field_type()`

- IddObject\$field_note()
- IddObject\$field_unit()
- IddObject\$field_default()
- IddObject\$field_choice()
- IddObject\$field_range()
- IddObject\$field_relation()
- IddObject\$field_possible()
- IddObject\$sis_valid_field_num()
- IddObject\$sis_extensible_index()
- IddObject\$sis_valid_field_name()
- IddObject\$sis_valid_field_index()
- IddObject\$sis_autosizable_field()
- IddObject\$sis_autocalculatable_field()
- IddObject\$sis_numeric_field()
- IddObject\$sis_real_field()
- IddObject\$sis_integer_field()
- IddObject\$sis_required_field()
- IddObject\$has_ref()
- IddObject\$has_ref_to()
- IddObject\$has_ref_by()
- IddObject\$to_table()
- IddObject\$to_string()
- IddObject\$print()

Method new(): Create an IddObject object

Usage:

```
IddObject$new(class, parent)
```

Arguments:

class A single integer specifying the class index or a single string specifying the class name.

parent An [Idd](#) object or a valid input for [use_idd\(\)](#).

Details: Note that an IddObject can be created from the parent [Idd](#) object, using [\\$object\(\)](#), [idd_object](#) and other equivalent.

Returns: An IddObject object.

Examples:

```
\dontrun{
surf <- IddObject$new("BuildingSurface:Detailed", use_idd(8.8, download = "auto"))
}
```

Method version(): Get the version of parent Idd

Usage:

```
IddObject$version()
```

Details: \$version() returns the version of parent Idd in a `base::numeric_version()` format. This makes it easy to direction compare versions of different IddObjects, e.g. `iddobj1$version() > 8.6` or `iddobj1$version() > iddobj2$version()`.

Returns: A `base::numeric_version()` object.

Examples:

```
\dontrun{
# get version
surf$version()
}
```

Method `parent()`: Get parent Idd

Usage:

```
IddObject$parent()
```

Details: \$parent() returns parent Idd object.

Returns: A Idd object.

Examples:

```
\dontrun{
surf$parent()
}
```

Method `group_name()`: Get the group name

Usage:

```
IddObject$group_name()
```

Details: \$group_name() returns the group name of current IddObject.

Returns: A single string.

Examples:

```
\dontrun{
surf$group_name()
}
```

Method `group_index()`: Get the group index

Usage:

```
IddObject$group_index()
```

Details: \$group_index() returns the group index of current IddObject. A group index is just an integer indicating its appearance order in the Idd.

Returns: A single integer.

Examples:

```
\dontrun{
surf$group_index()
}
```

Method `class_name()`: Get the class name of current IddObject

Usage:

```
IddObject$class_name()
```

Details: `$class_name()` returns the class name of current IddObject.

Returns: A single string.

Examples:

```
\dontrun{  
surf$class_name()  
}
```

Method `class_index()`: Get the class index

Usage:

```
IddObject$class_index()
```

Details: `$class_index()` returns the class index of current IddObject. A class index is just an integer indicating its appearance order in the [Idd](#).

Returns: A single integer.

Examples:

```
\dontrun{  
surf$class_index()  
}
```

Method `class_format()`: Get the class format

Usage:

```
IddObject$class_format()
```

Details: `$class_format()` returns the format of this IDD class. This format indicator is currently not used by `eplusr`.

Returns: A single character.

Examples:

```
\dontrun{  
surf$class_format()  
}
```

Method `min_fields()`: Get the minimum field number of current class

Usage:

```
IddObject$min_fields()
```

Details: `$min_fields()` returns the minimum fields required for current class. If no required, 0 is returned.

Returns: A single integer.

Examples:

```
\dontrun{
surf$num_fields()
}
```

Method num_fields(): Get the total field number of current class

Usage:

```
IddObject$num_fields()
```

Details: \$num_fields() returns current total number of fields in current class.

Returns: A single integer.

Examples:

```
\dontrun{
surf$num_fields()
}
```

Method memo(): Get the memo string of current class

Usage:

```
IddObject$memo()
```

Details: \$memo() returns memo of current class, usually a brief description of this class.

Returns: A character vector.

Examples:

```
\dontrun{
surf$memo()
}
```

Method num_extensible(): Get the field number of the extensible group in current class

Usage:

```
IddObject$num_extensible()
```

Details: \$num_extensible() returns the field number of the extensible group in current class.

An extensible group is a set of fields that should be treated as a whole, such like the X, Y and Z vertices of a building surfaces. An extensible group should be added or deleted together.

If there is no extensible group in current class, 0 is returned.

Returns: A single integer.

Examples:

```
\dontrun{
surf$num_extensible()
}
```

Method first_extensible_index(): Get the minimum field number of current class

Usage:

```
IddObject$first_extensible_index()
```

Details: \$first_extensible_index() returns the field index of first extensible field in current class. An extensible group is a set of fields that should be treated as a whole, such like the X, Y and Z vertices of a building surfaces. An extensible group should be added or deleted together. If there is no extensible group in current class, 0 is returned.

Returns: A single integer.

Examples:

```
\dontrun{
surf$first_extensible_index()
}
```

Method extensible_group_num(): Get the number of extensible groups in current class

Usage:

```
IddObject$extensible_group_num()
```

Details: \$extensible_group_num() returns the number of extensible groups in current class. An extensible group is a set of fields that should be treated as a whole, such like the X, Y and Z vertices of a building surfaces. An extensible group should be added or deleted together. If there is no extensible group in current class, 0 is returned.

Returns: A single integer.

Examples:

```
\dontrun{
surf$extensible_group_num()
}
```

Method add_extensible_group(): Add extensible groups in current class

Usage:

```
IddObject$add_extensible_group(num = 1L)
```

Arguments:

num An integer indicating the number of extensible groups to be added.

Details: \$add_extensible_groups() adds extensible groups in this class.

An extensible group is a set of fields that should be treated as a whole, such like the X, Y and Z vertices of a building surfaces. An extensible group should be added or deleted together. An error will be issued if current class contains no extensible group.

Returns: The modified IddObject itself.

Examples:

```
\dontrun{
# field number before adding
surf$num_fields()
# extensible group number before adding
surf$extensible_group_num()
}
```

```
# add 2 more extensible groups
surf$add_extensible_group(2)

# field number after adding
surf$num_fields()
# extensible group number after adding
surf$extensible_group_num()
}
```

Method `del_extensible_group()`: Delete extensible groups in current class

Usage:

```
IddObject$del_extensible_group(num = 1L)
```

Arguments:

`num` An integer indicating the number of extensible groups to be deleted.

Details: `$del_extensible_groups()` deletes extensible groups in this class.

An extensible group is a set of fields that should be treated as a whole, such like the X, Y and Z vertices of a building surfaces. An extensible group should be added or deleted together.

An error will be issued if current class contains no extensible group.

Returns: The modified IddObject itself.

Examples:

```
\dontrun{
# field number before deleting
surf$num_fields()
# extensible group number before deleting
surf$extensible_group_num()

# delete 2 more extensible groups
surf$del_extensible_group(2)

# field number after deleting
surf$num_fields()
# extensible group number after deleting
surf$extensible_group_num()
}
```

Method `has_name()`: Check if current class has name attribute

Usage:

```
IddObject$has_name()
```

Details: `$has_name()` return TRUE if current class has name attribute, and FALSE otherwise.

A class with name attribute means that objects in this class can have names.

Returns: A single logical value (TRUE or FALSE).

Examples:

```
\dontrun{
surf$has_name()
}
```

Method is_required(): Check if current class is required

Usage:

```
IddObject$is_required()
```

Details: \$is_required() returns TRUE if current class is required and FALSE otherwise.

A required class means that for any model, there should be at least one object in this class. One example is Building class.

Returns: A single logical value (TRUE or FALSE).

Examples:

```
\dontrun{
surf$is_required()
}
```

Method is_unique(): Check if current class is unique

Usage:

```
IddObject$is_unique()
```

Details: \$is_unique() returns TRUE if current class is unique and FALSE otherwise.

A unique class means that for any model, there should be at most one object in this class. One example is Building class.

Returns: A single logical value (TRUE or FALSE).

Examples:

```
\dontrun{
surf$is_unique()
}
```

Method is_extensible(): Check if current class is extensible

Usage:

```
IddObject$is_extensible()
```

Details: \$is_extensible() returns TRUE if current class is extensible and FALSE otherwise.

A extensible class means that there are certain number of fields in this class that can be dynamically added or deleted, such like the X, Y and Z vertices of a building surface.

Returns: A single logical value (TRUE or FALSE).

Examples:

```
\dontrun{
surf$is_extensible()
}
```

Method `field_name()`: Get field names

Usage:

```
IddObject$field_name(
  index = NULL,
  unit = FALSE,
  in_ip = eplusr_option("view_in_ip"),
  lower = FALSE
)
```

Arguments:

`index` An integer vector of field indices. If `NULL`, names of all fields in this class are returned.

Default: `NULL`.

`unit` If `TRUE`, the units of those fields are also returned. Default: `FALSE`.

`in_ip` If `in_ip`, corresponding imperial units are returned. It only has effect when `unit` is `TRUE`. Default: `eplusr_option("view_in_ip")`.

`lower` If `TRUE`, "lower-style" names are returned, i.e. all spaces and dashes is replaced by underscores. "lower-style" names are useful when use them as filed names in `$set_value()` in `IdfObject` class and `$set_object()` in `Idf` class. Default: `FALSE`.

Details: `$field_name()` returns a character vector of names of fields specified by field indices in current class.

Returns: A character vector.

Examples:

```
\dontrun{
# get all field names
surf$field_name()

# get field units also
surf$field_name(unit = TRUE)

# get field units in IP
surf$field_name(unit = TRUE)

# change field name to lower-style
surf$field_name(unit = TRUE, in_ip = TRUE)
}
```

Method `field_index()`: Get field indices

Usage:

```
IddObject$field_index(name = NULL)
```

Arguments:

`name` A character vector of field names. Can be in "lower-style", i.e. all spaces and dashes is replaced by underscores. If `NULL`, indices of all fields in this class are returned. Default: `NULL`.

Details: `$field_index()` returns an integer vector of names of fields specified by field names in current class.

Returns: An integer vector.

Examples:

```
\dontrun{
# get all field indices
surf$field_index()

# get field indices for specific fields
surf$field_index(c("number of vertices", "vertex 10 z-coordinate"))
}
```

Method `field_type()`: Get field types

Usage:

```
IddObject$field_type(which = NULL)
```

Arguments:

`which` An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: `$field_type()` returns a character vector of field types of specified fields in current class.

All possible values are:

- "integer"
- "real"
- "alpha" (arbitrary string)
- "choice" (alpha with specific list of choices)
- "object-list" (link to a list of objects defined elsewhere)
- "external-list" (uses a special list from an external source)
- "node" (name used in connecting HVAC components).

Returns: A character vector.

Examples:

```
\dontrun{
# get all field types
surf$field_type()

# get field types for specific fields
surf$field_type(c("name", "zone name", "vertex 10 z-coordinate"))
}
```

Method `field_note()`: Get field notes

Usage:

```
IddObject$field_note(which = NULL)
```

Arguments:

`which` An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: `$field_note()` returns a list of character vectors that contains field notes of specified fields in current class, usually serving as field descriptions. If no notes are found for current fields, NULL is returned.

Returns: A list of character vectors.

Examples:

```
\dontrun{
# get all field notes
surf$field_note()

# get field types for specific fields
surf$field_note(c("name", "zone name", "vertex 10 z-coordinate"))
}
```

Method `field_unit()`: Get field units

Usage:

```
IddObject$field_unit(which = NULL, in_ip = eplusr_option("view_in_ip"))
```

Arguments:

`which` An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

`in_ip` If `in_ip`, corresponding imperial units are returned. Default: `eplusr_option("view_in_ip")`.

Details: `$field_unit()` returns a character vector that contains units of specified fields in current class. If there is no unit found for current field, NA is returned.

Returns: A character vector.

Examples:

```
\dontrun{
# get all field units
surf$field_unit()

# get field units for specific fields
surf$field_unit(c("name", "zone name", "vertex 10 z-coordinate"))
}
```

Method `field_default()`: Get field default value

Usage:

```
IddObject$field_default(which = NULL, in_ip = eplusr_option("view_in_ip"))
```

Arguments:

`which` An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

`in_ip` If `in_ip`, values in corresponding imperial units are returned. Default: `eplusr_option("view_in_ip")`.

Details: `$field_default()` returns a list that contains default values of specified fields in current class. If there is no default value found for current field, NA is returned.

Returns: A character vector.

Examples:

```
\dontrun{
# get all field default values
surf$field_default()

# get default values for specific fields
surf$field_default(c("name", "zone name", "vertex 10 z-coordinate"))
}
```

Method `field_choice()`: Get choices of field values

Usage:

```
IddObject$field_choice(which = NULL)
```

Arguments:

which An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: `$field_value()` returns a list of character vectors that contains choices of specified field values in current class. If there is no choice found for current field, NULL is returned.

Returns: A list of character vectors.

Examples:

```
\dontrun{
# get all field value choices
surf$field_choice()

# get field value choices for specific fields
surf$field_choice(c("name", "sun exposure", "wind exposure"))
}
```

Method `field_range()`: Get field value ranges

Usage:

```
IddObject$field_range(which = NULL)
```

Arguments:

which An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: `$field_range()` returns a list of value ranges of specified fields in current class.

Every range has four components:

- *minimum*: lower limit
- *lower_incbounds*: TRUE if the lower limit should be included
- *maximum*: upper limit
- *upper_incbounds*: TRUE if the upper limit should be included

For fields of character type,

- minimum and maximum are always set to NA
- lower_incbounds and upper_incbounds are always set to FALSE

For fields of numeric types with no specified ranges,

- minimum is set to -Inf
- lower_incbounds is set to FALSE
- upper is set to Inf
- upper_incbounds is set to FALSE

The field range is printed in number interval denotation.

Returns: A list of ranges.

Examples:

```
\dontrun{
# get all field value ranges
surf$field_range()

# get value ranges for specific fields
surf$field_range(c("name", "number of vertices", "vertex 10 z-coordinate"))
}
```

Method `field_relation()`: Extract the relationship among fields

Usage:

```
IddObject$field_relation(
  which = NULL,
  direction = c("all", "ref_by", "ref_to")
)
```

Arguments:

`which` An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

`direction` The relation direction to extract. Should be one of "all", "ref_to" or "ref_by".

Details: Many fields in `Idd` can be referred by others. For example, the Outside Layer and other fields in Construction class refer to the Name field in Material class and other material related classes. Here it means that the Outside Layer field **refers to** the Name field and the Name field is **referred by** the Outside Layer.

`$field_relation()` provides a simple interface to get this kind of relation. It takes a field specification and a relation direction, and returns an `IddRelation` object which contains data presenting such relation above.

`$field_relation()` returns a list of references for those fields that have the object-list and/or reference and reference-class-name attribute. Basically, it is a list of two elements `ref_to` and `ref_by`. Underneath, `ref_to` and `ref_by` are `data.tables` which contain source field data and reference field data with custom printing method. For instance, if `iddobj$field_relation(c(1,2),"ref_to")` gives results below:

```
-- Refer to Others -----
+- Field: <1: Field 1>
| v~~~~~
| \- Class: <Class 2>
```

```
|      \- Field: <2: Field 2>
|
\-- Field: <2: Field 2>
```

This means that Field 2 in current class does not refer to any other fields. But Field 1 in current class refers to Field 2 in class named Class 2.

Returns: An IddRelation object.

Examples:

```
\dontrun{
# get field relation for specific fields
surf$field_relation(c("name", "zone name", "vertex 10 z-coordinate"))
}
```

Method `field_possible()`: Get field possible values

Usage:

```
IddObject$field_possible(which = NULL, in_ip)
```

Arguments:

`which` An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

`in_ip` Deprecated. The field value unit is determined by `eplusr_option("view_in_ip")`.

Details: `$field_possible()` returns all possible values for specified fields, including auto-value (Autosize, Autocalculate, and NA if not applicable), and results from `$field_default()`, `$field_range()`, `$field_choice()`. Underneath, it returns a `data.table` with custom printing method. For instance, if `iddobj$field_possible(c(4,2))` gives results below:

```
-- 4: Field 4 -----
* Auto value: <NA>
* Default: <NA>
* Choice:
  - "Key1"
  - "Key2"

-- 2: Field 2 -----
* Auto value: "Autosize"
* Default: 2
* Choice: <NA>
```

This means that Field 4 in current class cannot be "autosized" or "autocalculated", and it does not have any default value. Its value should be a choice from "Key1" or "Key2". For Field 2 in current class, it has a default value of 2 but can also be filled with value "Autosize".

Returns: A `IddFieldPossible` object which is a `data.table::data.table()` with 9 columns.

Examples:

```
\dontrun{
# get field possible values for specific fields
surf$field_possible(6:10)
}
```

Method `is_valid_field_num()`: Check if input is a valid field number

Usage:

```
IddObject$is_valid_field_num(num)
```

Arguments:

`num` An integer vector to test.

Details: `$is_valid_field_num()` returns TRUE if input `num` is acceptable as a total number of fields in this class. Extensible property is considered.

For instance, the total number of fields defined in IDD for class `BuildingSurfaces:Detailed` is 390. However, 396 is still a valid field number for this class as the number of field in the extensible group is 3.

Returns: A logical vector.

Examples:

```
\dontrun{
surf$is_valid_field_num(c(10, 14, 100))
}
```

Method `is_extensible_index()`: Check if input field index indicates an extensible field

Usage:

```
IddObject$is_extensible_index(index)
```

Arguments:

`index` An integer vector of field indices.

Details: `$is_extensible_index()` returns TRUE if input `index` indicates an index of extensible field in current class.

Extensible fields mean that these fields can be dynamically added or deleted, such like the X, Y and Z vertices of a building surface.

Returns: A logical vector.

Examples:

```
\dontrun{
surf$is_extensible_index(c(10, 14, 100))
}
```

Method `is_valid_field_name()`: Check if input character is a valid field name

Usage:

```
IddObject$is_valid_field_name(name, strict = FALSE)
```

Arguments:

`name` A character vector to test.

`strict` If TRUE, only exact match is accepted. Default: FALSE.

Details: `$is_valid_field_name()` returns TRUE if `name` is a valid field name **WITHOUT** unit. Note `name` can be given in underscore style, e.g. "outside_layer" is equivalent to "Outside Layer".

Returns: A logical vector.

Examples:

```
\dontrun{
surf$is_valid_field_name(c("name", "sun_exposure"))

# exact match
surf$is_valid_field_name(c("Name", "Sun_Exposure"), strict = TRUE)
}
```

Method *is_valid_field_index()*: Check if input integer is a valid field index

Usage:

```
IddObject$is_valid_field_index(index)
```

Arguments:

index An integer vector to test.

Details: *is_valid_field_index()* returns TRUE if *index* is a valid field index. For extensible class, TRUE is always returned.

Returns: A logical vector.

Examples:

```
\dontrun{
surf$is_valid_field_index(1:10)
}
```

Method *is_autosizable_field()*: Check if input field can be autosized

Usage:

```
IddObject$is_autosizable_field(which = NULL)
```

Arguments:

which An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: *is_autosizable_field()* returns TRUE if input field can be assigned to autosize.

Returns: A logical vector.

Examples:

```
\dontrun{
surf$is_autosizable_field()

surf$is_autosizable_field(c("name", "sun_exposure"))
}
```

Method *is_autocalculatable_field()*: Check if input field can be autocalculated

Usage:

```
IddObject$is_autocalculatable_field(which = NULL)
```

Arguments:

which An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: \$is_autocalculatable_field() returns TRUE if input field can be assigned to autocalculate.

Returns: A logical vector.

Examples:

```
\dontrun{
surf$is_autocalculatable_field()

surf$is_autocalculatable_field(c("name", "sun_exposure"))
}
```

Method is_numeric_field(): Check if input field value should be numeric

Usage:

```
IddObject$is_numeric_field(which = NULL)
```

Arguments:

which An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: \$is_numeric_field() returns TRUE if the value of input field should be numeric (an integer or a real number).

Returns: A logical vector.

Examples:

```
\dontrun{
surf$is_numeric_field()

surf$is_numeric_field(c("name", "sun_exposure"))
}
```

Method is_real_field(): Check if input field value should be a real number

Usage:

```
IddObject$is_real_field(which = NULL)
```

Arguments:

which An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: \$is_real_field() returns TRUE if the field value should be a real number but not an integer.

Returns: A logical vector.

Examples:

```
\dontrun{
surf$is_real_field()

surf$is_real_field(c("name", "number of vertices"))
}
```

Method is_integer_field(): Check if input field value should be an integer

Usage:

```
IddObject$is_integer_field(which = NULL)
```

Arguments:

which An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: \$is_real_field() returns TRUE if the field value should be an integer.

Returns: A logical vector.

Examples:

```
\dontrun{
surf$is_integer_field()

surf$is_integer_field(c("name", "number of vertices"))
}
```

Method is_required_field(): Check if input field is required

Usage:

```
IddObject$is_required_field(which = NULL)
```

Arguments:

which An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: \$is_required_field() returns TRUE if the field is required.

Returns: A logical vector.

Examples:

```
\dontrun{
surf$is_required_field()

surf$is_required_field(c("name", "number of vertices"))
}
```

Method has_ref(): Check if input field can refer to or can be referred by other fields

Usage:

```
IddObject$has_ref(which = NULL)
```

Arguments:

which An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: \$has_ref() returns TRUE if input field refers to or can be referred by other fields.

Returns: A logical vector.

Examples:

```
\dontrun{
surf$has_ref()

surf$has_ref(c("name", "zone name"))
}
```

Method has_ref_to(): Check if input field can refer to other fields

Usage:

```
IddObject$has_ref_to(which = NULL)
```

Arguments:

which An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: \$has_ref_to() returns TRUE if input field can refer to other fields.

Returns: A logical vector.

Examples:

```
\dontrun{
surf$has_ref_to()

surf$has_ref_to(c("name", "zone name"))
}
```

Method has_ref_by(): Check if input field can be referred by other fields

Usage:

```
IddObject$has_ref_by(which = NULL)
```

Arguments:

which An integer vector of field indices or a character vector of field names in current class. If NULL, all fields in this class are used. Default: NULL.

Details: \$has_ref_by() returns TRUE if input field can be referred by other fields.

Returns: A logical vector.

Examples:

```
\dontrun{
surf$has_ref_by()

surf$has_ref_by(c("name", "zone name"))
}
```

Method to_table(): Format an IddObject as a data.frame

Usage:

```
IddObject$to_table(all = FALSE)
```

Arguments:

all If TRUE, all available fields defined in IDD for specified class will be returned. If FALSE, only the minimum field number is returned. Default: FALSE.

Details: \$to_table() returns a [data.table](#) that contains basic data of current class. The returned [data.table](#) has 3 columns:

- class: Character type. Current class name.
- index: Integer type. Field indexes.
- field: Character type. Field names.

Returns: A [data.table](#) with 3 columns.

Examples:

```
\dontrun{
surf$to_table()

surf$to_table(TRUE)
}
```

Method to_string(): Format an IdfObject as a character vector

Usage:

```
IddObject$to_string(comment = NULL, leading = 4L, sep_at = 29L, all = FALSE)
```

Arguments:

comment A character vector to be used as comments of returned string format object.

leading Leading spaces added to each field. Default: 4L.

sep_at The character width to separate value string and field string. Default: 29L which is the same as IDF Editor.

all If TRUE, all available fields defined in IDD for specified class will be returned. Default: FALSE.

Details: \$to_string() returns the text format of current class. The returned character vector can be pasted into an IDF file as an empty object of specified class.

Returns: A character vector.

Examples:

```
\dontrun{
# get text format of class BuildingSurface:Detailed
surf$to_string()

# tweak output formatting
surf$to_string(leading = 0, sep_at = 0)

# add comments
surf$to_string(c("This", "will", "be", "comments"))
}
```

Method print(): Print IddObject object

Usage:

```
IddObject#print(brief = FALSE)
```

Arguments:

brief If TRUE, only class name part is printed. Default: FALSE.

Details: \$print() prints the IddObject object giving the information of class name, class properties, field indices and field names.

\$print() prints the IddObject. Basically, the print output can be divided into 4 parts:

- CLASS: IDD class name of current object in format <IddObject: CLASS>.
- MEMO: brief description of the IDD class.
- PROPERTY: properties of the IDD class, including name of group it belongs to, whether it is an unique or required class and current total fields. The fields may increase if the IDD class is extensible, such as Branch, ZoneList and etc.
- FIELDS: fields of current IDD class. Required fields are marked with stars (*). If the class is extensible, only the first extensible group will be printed and two ellipses will be shown at the bottom. Fields in the extensible group will be marked with an arrow down surrounded by angle brackets (<v>).

Returns: The IddObject object itself, invisibly.

Examples:

```
\dontrun{
surf

surf#print(brief = TRUE)
}
```

Note

Some classes have special format when saved in the IDFEditor with the special format option enabled. Those special format includes "singleLine", "vertices", "compactSchedule", "fluidProperties", "viewFactors" and "spectral". eplusr can handle all those format when parsing IDF files. However, when saved, all classes are formatted in standard way.

This number may change if the class is extensible and after \$add_extensible_group() or \$del_extensible_group().

The type of each default value will be consistent with field definition. However, for numeric fields with default values being "autosize" or "autocalculate", the type of returned values will be character.

idd_object

Create an IddObject object.

Description

idd_object() takes a parent Idd object, a class name, and returns a corresponding [IddObject](#). For details, see [IddObject](#).

Usage

```
idd_object(parent, class)
```

Arguments

parent	An Idd object or a valid input for use_idd() .
class	A valid class name (a string).

Value

An [IddObject](#) object.

Examples

```
## Not run:
idd <- use_idd(8.8, download = "auto")

# get an IddObject using class name
idd_object(idd, "Material")
idd_object(8.8, "Material")

## End(Not run)
```

Idf

Read, Modify, and Run an EnergyPlus Model

Description

eplusr provides parsing EnergyPlus Input Data File (IDF) files and strings in a hierarchical structure, which was extremely inspired by [OpenStudio utilities library](#), but with total different data structure under the hook.

Details

eplusr uses `Idf` class to present the whole IDF file and use `IddObject` to present a single object in IDF. Both `Idf` and `IddObject` contain member functions for helping modify the data in IDF so it complies with the underlying IDD (EnergyPlus Input Data Dictionary).

Under the hook, eplusr uses a SQL-like structure to store both IDF and IDD data in different `data.table::data.tables`. So to modify an EnergyPlus model in eplusr is equal to change the data in those IDF tables accordingly, in the context of specific IDD data. This means that a corresponding `Idd` object is needed whenever creating an `Idf` object. eplusr provides several [helpers](#) to easily download IDD files and create `Idd` objects.

All IDF reading process starts with function `read_idf()` which returns an `Idf` object. `Idf` class provides lots of methods to programmatically query and modify EnergyPlus models.

Internally, the powerful `data.table` package is used to speed up the whole IDF parsing process and store the results. Under the hook, eplusr uses a SQL-like structure to store both IDF and IDD data in `data.table::data.table` format. Every IDF will be parsed and stored in three tables:

- `object`: contains object IDs, names and comments.
- `value`: contains field values
- `reference`: contains cross-reference data of field values.

Methods

Public methods:

- `Idf$new()`
- `Idf$version()`

- Idf\$path()
- Idf\$group_name()
- Idf\$class_name()
- Idf\$is_valid_group()
- Idf\$is_valid_class()
- Idf\$definition()
- Idf\$object_id()
- Idf\$object_name()
- Idf\$object_num()
- Idf\$is_valid_id()
- Idf\$is_valid_name()
- Idf\$object()
- Idf\$objects()
- Idf\$object_unique()
- Idf\$objects_in_class()
- Idf\$objects_in_group()
- Idf\$object_relation()
- Idf\$objects_in_relation()
- Idf\$search_object()
- Idf\$dup()
- Idf\$add()
- Idf\$set()
- Idf\$del()
- Idf\$rename()
- Idf\$insert()
- Idf\$load()
- Idf\$update()
- Idf\$paste()
- Idf\$search_value()
- Idf\$replace_value()
- Idf\$validate()
- Idf\$is_valid()
- Idf\$to_string()
- Idf\$to_table()
- Idf\$is_unsaved()
- Idf\$save()
- Idf\$run()
- Idf\$last_job()
- Idf\$print()
- Idf\$clone()

Method new(): Create an Idf object

Usage:

```
Idf$new(path, idd = NULL)
```

Arguments:

path Either a path, a connection, or literal data (either a single string or a raw vector) to an EnergyPlus Input Data File (IDF). If a file path, that file usually has a extension .idf.

idd Any acceptable input of `use_idd()`. If NULL, which is the default, the version of IDF will be passed to `use_idd()`. If the input is an .ddy file which does not have a version field, the latest version of `Idf` cached will be used.

Details: It takes an EnergyPlus Input Data File (IDF) as input and returns an `Idf` object. Currently, `Imf` file is not fully supported. All `EpMacro` lines will be treated as normal comments of the nearest downwards object. If input is an `Imf` file, a warning will be given during parsing. It is recommended to convert the `Imf` file to an `Idf` file and use `ParametricJob` class to conduct parametric analysis.

Returns: An `Idf` object.

Examples:

```
\dontrun{
# example model shipped with eplusr from EnergyPlus v8.8
path_idf <- system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr") # v8.8

# If neither EnergyPlus v8.8 nor Idd v8.8 was found, error will
# occur. If Idd v8.8 is found, it will be used automatically.
idf <- Idf$new(path_idf)

# argument `idd` can be specified explicitly using `use_idd()`
idf <- Idf$new(path_idf, idd = use_idd(8.8))

# you can set `download` argument to "auto" in `use_idd()` if you
# want to automatically download corresponding IDD file when
# necessary
idf <- Idf$new(path_idf, use_idd(8.8, download = "auto"))

# Besides use a path to an IDF file, you can also provide IDF in literal
# string format
string_idf <-
  "
  Version, 8.8;
  Building,
    Building;                !- Name
  "

Idf$new(string_idf, use_idd(8.8, download = "auto"))
}
```

Method `version()`: Get the version of current `Idf`

Usage:

Idf\$version()

Details: \$version() returns the version of current Idf in a `base::numeric_version()` format. This makes it easy to direction compare versions of different Idfs, e.g. `idf$version() > 8.6` or `idf1$version() > idf2$version()`.

Returns: A `base::numeric_version()` object.

Examples:

```
\dontrun{
# get version
idf$version()
}
```

Method path(): Get the file path of current Idf

Usage:

Idf\$path()

Details: \$path() returns the full path of current Idf or NULL if the Idf object is created using a character vector and not saved locally.

Returns: NULL or a single string.

Examples:

```
\dontrun{
# get path
idf$path()

# return `NULL` if Idf is not created from a file
Idf$new("Version, 8.8;\n")$path()
}
```

Method group_name(): Get names of groups

Usage:

Idf\$group_name(all = FALSE, sorted = TRUE)

Arguments:

all If FALSE, only names of groups in current Idf object will be returned. If TRUE, all group names in the underlying Idd will be returned. Default: FALSE.

sorted Only applicable when all is FALSE. If TRUE, duplications in returned group or class names are removed, and unique names are further sorted according to their occurrences in the underlying Idd. Default: TRUE.

Details: \$group_name() returns names of groups current Idf contains or the underlying Idd object contains.

Returns: A character vector.

Examples:

```

\dontrun{
# get names of all groups Idf contains
idf$group_name()

# get group name of each object in Idf
idf$group_name(sorted = FALSE)

# get names of all available groups in underlying Idd
idf$group_name(all = TRUE)
}

```

Method `class_name()`: Get names of classes

Usage:

```
Idf$class_name(all = FALSE, sorted = TRUE, by_group = FALSE)
```

Arguments:

`all` If FALSE, only names of classes in current Idf object will be returned. If TRUE, all class names in the underlying Idd will be returned. Default: FALSE.

`sorted` Only applicable when `all` is FALSE. If TRUE, duplications in returned group or class names are removed, and unique names are further sorted according to their occurrences in the underlying Idd. Default: TRUE.

`by_group` Only applicable when `all` or `sorted` is TRUE. If TRUE, a list is returned which separates class names by the group they belong to.

Details: `$class_name()` returns names of classes current Idf contains or the underlying Idd object contains.

Returns: A character vector if `by_group` is FALSE and a list of character vectors when `by_group` is TRUE.

Examples:

```

\dontrun{
# get names of all classes in Idf
idf$class_name()

# get names of all classes grouped by group names in Idf
idf$class_name(by_group = TRUE)

# get class name of each object in Idf
idf$class_name(sorted = FALSE)

# get names of all available classes in underlying Idd
idf$class_name(all = TRUE)

# get names of all available classes grouped by group names in
# underlying Idd
idf$class_name(all = TRUE, by_group = TRUE)
}

```

Method `is_valid_group()`: Check if elements in input character vector are valid group names.

Usage:

```
Idf$is_valid_group(group, all = FALSE)
```

Arguments:

`group` A character vector to check.

`all` If FALSE, check if input characters are valid group names for current Idf. If TRUE, check if input characters are valid group names for underlying Idd. Default: FALSE

Details: `$is_valid_group()` returns TRUEs if given character vector contains valid group names in the context of current Idf (when `all` is FALSE) or current underlying Idd (when `all` is TRUE). Note that case-sensitive matching is performed, which means that "Location and Climate" is a valid group name but "location and climate" is not.

Returns: A logical vector with the same length as input character vector.

Examples:

```
\dontrun{
# check if input is a valid group name in current Idf
idf$is_valid_group(c("Schedules", "Compliance Objects"))

# check if input is a valid group name in underlying Idd
idf$is_valid_group(c("Schedules", "Compliance Objects"), all = TRUE)
}
```

Method `is_valid_class()`: Check if elements in input character vector are valid class names.

Usage:

```
Idf$is_valid_class(class, all = FALSE)
```

Arguments:

`class` A character vector to check.

`all` If FALSE, check if input characters are valid class names for current Idf. If TRUE, check if input characters are valid class names for underlying Idd. Default: FALSE

Details: `$is_valid_class()` returns TRUEs if given character vector contains valid class names in the context of current Idf (when `all` is FALSE) or current underlying Idd (when `all` is TRUE), and FALSEs otherwise.

Note that case-sensitive matching is performed, which means that "Version" is a valid class name but "version" is not.

Returns: A logical vector with the same length as input character vector.

Examples:

```
\dontrun{
# check if input is a valid class name in current Idf
idf$is_valid_class(c("Building", "ShadowCalculation"))

# check if input is a valid class name in underlying Idd
idf$is_valid_class(c("Building", "ShadowCalculation"), all = TRUE)
}
```

Method `definition()`: Get the [IddObject](#) object for specified class.

Usage:

```
Idf$definition(class)
```

Arguments:

`class` A **single** string of valid class name in current [Idd](#).

Details: `$definition()` returns an [IddObject](#) of given class. [IddObject](#) contains all data used for parsing and creating an [IdfObject](#). For details, please see [IddObject](#) class.

Returns: An [IddObject](#) object.

Examples:

```
\dontrun{
# get the IddObject object for specified class
idf$definition("Version")
}
```

Method `object_id()`: Get the unique ID for each object in specified classes in the [Idf](#).

Usage:

```
Idf$object_id(class = NULL, simplify = FALSE)
```

Arguments:

`class` A character vector that contains valid class names for current [Idf](#) object. If `NULL`, all classes in current [Idf](#) object are used. Default: `NULL`.

`simplify` If `TRUE`, an integer vector contains object IDs of all specified classes is returned. If `FALSE`, a named list that contains object IDs for each specified class is returned. Default: `FALSE`.

Details: In [Idf](#), each object is assigned with an integer as an universally unique identifier (UUID) in the context of current [Idf](#). UUID is not reused even if the object associated is deleted.

`$object_id()` returns an integer vector (when `simplify` is `TRUE`) or a named list (when `simplify` is `FALSE`) of integer vectors that contain object IDs in each specified class. The returned list is named using specified class names.

Returns: An integer vector (when `simplify` is `TRUE`) or a named list of integer vectors (when `simplify` is `FALSE`).

Examples:

```
\dontrun{
# get IDs of all objects in current Idf object
idf$object_id()

# get IDs of all objects in current Idf object, and merge them into a
# single integer vector
idf$object_id(simplify = TRUE)

# get IDs of objects in class Version and Zone
idf$object_id(c("Version", "Zone"))
```

```
# get IDs of objects in class Version and Zone, and merge them into a
# single integer vector
idf$object_id(c("Version", "Zone"), simplify = TRUE)
}
```

Method `object_name()`: Get names for objects in specified classes in the Idf.

Usage:

```
Idf$object_name(class = NULL, simplify = FALSE)
```

Arguments:

`class` A character vector that contains valid class names for current Idf. If NULL, all classes in current Idf are used. Default: NULL.

`simplify` If TRUE, a character vector contains object names of all specified classes is returned. If FALSE, a named list that contains a character vector for each specified class is returned. Default: FALSE.

Details: In Idf, each object is assigned with a single string as the name for it, if the class it belongs to has name attribute, e.g. class RunPeriod, Material and etc. That name should be unique among all objects in that class. EnergyPlus will fail with an error if duplications are found among object names in a class.

`$object_name()` returns a character vector (when `simplify` is TRUE) or a named list (when `simplify` is FALSE) of character vectors that contain object IDs in each specified class. The returned list is named using specified class names. If specified class does not have name attribute, NAs are returned.

Returns: A character vector (when `simplify` is TRUE) or a named list of character vectors (when `simplify` is FALSE).

Examples:

```
\dontrun{
# get names of all objects in current Idf object
idf$object_name()

# get names of all objects in current Idf object, and merge them into
# a single character vector
idf$object_name(simplify = TRUE)

# get names of objects in class Version and Zone
idf$object_name(c("Version", "Zone"))

# get names of objects in class Version and Zone, and merge them into
# a single character vector
idf$object_name(c("Version", "Zone"), simplify = TRUE)
}
```

Method `object_num()`: Get number of objects in specified classes in the Idf object.

Usage:

```
Idf$object_num(class = NULL)
```

Arguments:

`class` A character vector that contains valid class names for underlying `Idd`. If `NULL`, all classes in current `Idf` are used, and the total object number is returned. Default: `NULL`.

Details: `$object_num()` returns an integer vector of object number in specified classes. `0` is returned if there is no object in that class.

Returns: An integer vector.

Examples:

```
\dontrun{
# get total number of objects
idf$object_num()

# get number of objects in class Zone and Schedule:Compact
idf$object_num(c("Zone", "Schedule:Compact"))
}
```

Method `is_valid_id()`: Check if elements in input integer vector are valid object IDs.

Usage:

```
Idf$is_valid_id(id)
```

Arguments:

`id` An integer vector to check.

Details: `$is_valid_id()` returns `TRUE`s if given integer vector contains valid object IDs in current `Idf` object.

Returns: A logical vector with the same length as input integer vector.

Examples:

```
\dontrun{
idf$is_valid_id(c(51, 1000))
}
```

Method `is_valid_name()`: Check if elements in input character vector are valid object names.

Usage:

```
Idf$is_valid_name(name)
```

Arguments:

`name` A character vector to check.

Details: `$is_valid_name()` returns `TRUE`s if given character vector contains valid object names in current `Idf` object.

Note that **case-insensitive** matching is performed, which means that "r0oF" is equivalent to "roof". This behavior is consistent in all methods that take object name(s) as input.

Returns: A logical vector with the same length as input character vector.

Examples:

```

\dontrun{
idf$isValid_name(c("Simple One Zone (Wireframe DXF)", "ZONE ONE", "a"))

# name matching is case-insensitive
idf$isValid_name(c("simple one zone (wireframe dxf)", "zone one", "a"))
}

```

Method `object()`: Extract an [IdfObject](#) object using object ID or name.

Usage:

```
Idf$object(which)
```

Arguments:

`which` A single integer specifying the object ID or a single string specifying the object name.

Details: `$object()` returns an [IdfObject](#) object specified by an object ID or name.

Note that unlike object ID, which is always unique across the whole Idf object, different objects can have the same name. If the name given matches multiple objects, an error is issued showing what objects are matched by the same name. This behavior is consistent in all methods that take object name(s) as input. In this case, it is suggested to directly use object ID instead of name.

Note that **case-insensitive** matching is performed for object names, which means that "rOoF" is equivalent to "roof". This behavior is consistent in all methods that take object name(s) as input.

Returns: An [IdfObject](#) object.

Examples:

```

\dontrun{
# get an object whose ID is 3
idf$object(3)

# get an object whose name is "simple one zone (wireframe dxf)"
# NOTE: object name matching is case-insensitive
idf$object("simple one zone (wireframe dxf)")
}

```

Method `objects()`: Extract multiple [IdfObject](#) objects using object IDs or names.

Usage:

```
Idf$objects(which)
```

Arguments:

`which` An integer vector specifying object IDs or a character vector specifying object names.

Details: `$objects()` returns a named list of [IdfObject](#) objects using object IDs or names. The returned list is named using object names.

Note that unlike object ID, which is always unique across the whole Idf object, different objects can have the same name. If the name given matches multiple objects, an error is issued showing what objects are matched by the same name. This behavior is consistent in all methods that take object name(s) as input. In this case, it is suggested to directly use object ID instead of name.

Note that **case-insensitive** matching is performed for object names, which means that "rOoF" is equivalent to "roof". This behavior is consistent in all methods that take object name(s) as input.

Returns: A named list of [IdfObject](#) objects.

Examples:

```
\dontrun{
# get objects whose IDs are 3 and 10
idf$objects(c(3,10))

# get objects whose names are "Simple One Zone (Wireframe DXF)" and "ZONE ONE"
# NOTE: object name matching is case-insensitive
idf$objects(c("Simple One Zone (Wireframe DXF)", "zone one"))
}
```

Method `object_unique()`: Extract the [IdfObject](#) in class with unique-object attribute.

Usage:

```
Idf$object_unique(class)
```

Arguments:

class A single string of valid class name for current Idf object.

Details: For each version of an Idf object, the corresponding underlying [Idd](#) describe how many objects can be defined in each class. Classes that have unique-object attribute can only hold a single object, e.g. Version, SimulationControl and etc. `$object_unique()` can be used to directly return the [IdfObject](#) in one unique-object class. An error will be issued if there are multiple objects in that class or input class is not an unique-object class. This makes sure that `$object_unique()` always returns a single [IdfObject](#).

Idf class also provides custom S3 method of `$` and `[[` to make it more convenient to get the [IdfObject](#) in unique-object class. Basically, `idf$ClassName` and `idf[["ClassName"]]`, where `ClassName` is a single valid class name, is equivalent to `idf$object_unique(ClassName)` if `ClassName` is an unique-object class. For convenience, underscore-style names are allowed when using `$`, e.g. `Site_Location` is equivalent to `Site:Location`. For instance, `idf$Site_Location` and also `idf[["Site_Location"]]` will both return the [IdfObjects](#) in `Site:Location` class. Note that unlike `$object_unique()`, `idf$ClassName` and `idf[["ClassName"]]` will directly return NULL instead of giving an error when `ClassName` is not a valid class name in current Idf object. This makes it possible to use `is.null(idf$ClassName)` to check if `ClassName` is a valid class or not.

Returns: An [IdfObject](#) object.

Examples:

```
\dontrun{
# get the SimulationControl object
idf$object_unique("SimulationControl")

# S3 "[[" and "$" can also be used
idf$SimulationControl
idf[["SimulationControl"]]
}
```

Method `objects_in_class()`: Extract all [IdfObject](#) objects in one class.

Usage:

```
Idf$objects_in_class(class)
```

Arguments:

class A single string of valid class name for current Idf object.

Details: \$objects_in_class() returns a named list of all [IdfObject](#) objects in specified class. The returned list is named using object names.

Idf class also provides custom S3 method of \$ and [[to make it more convenient to get all [IdfObject](#) objects in one class. Basically, idf\$ClassName and idf[["ClassName"]], where ClassName is a single valid class name, is equivalent to idf\$objects_in_class(ClassName) if ClassName is not an unique-object class. For convenience, *underscore-style* names are allowed, e.g. BuildingSurface_Detailed is equivalent to BuildingSurface:Detailed when using \$. For instance, idf\$BuildingSurface_Detailed and also idf[["BuildingSurface:Detailed"]] will both return all [IdfObject](#) objects in BuildingSurface:Detailed class. Note that unlike \$objects_in_class(), idf\$ClassName and idf[["ClassName"]] will directly return NULL instead of giving an error when ClassName is not a valid class name in current Idf object. This makes it possible to use is.null(idf\$ClassName) to check if ClassName is a valid class or not.

Returns: A named list of [IdfObject](#) objects.

Examples:

```
\dontrun{
# get all objects in Zone class
idf$objects_in_class("Zone")

# S3 "[" and "$" can also be used
idf$Zone
idf[["Zone"]]
}
```

Method objects_in_group(): Extract all [IdfObject](#) objects in one group.

Usage:

```
Idf$objects_in_group(group)
```

Arguments:

group A single string of valid group name for current Idf object.

Details: \$objects_in_group() returns a named list of all [IdfObject](#) objects in specified group. The returned list is named using object names.

Returns: A named list of [IdfObject](#) objects.

Examples:

```
\dontrun{
# get all objects in Schedules group
idf$objects_in_group("Schedules")
}
```

Method object_relation(): Extract the relationship between object field values.

Usage:

```
Idf$object_relation(
  which,
  direction = c("all", "ref_to", "ref_by", "node"),
  recursive = FALSE,
  depth = 1L
)
```

Arguments:

which A single integer specifying object ID or a single string specifying object name.

direction The relation direction to extract. Should be either "all", "ref_to", "ref_by" and "node".

recursive If TRUE, the relation is searched recursively. A simple example of recursive reference: one material named mat is referred by a construction named const, and const is also referred by a surface named surf. If recursive is TRUE, all relations above will be extracted.

depth Only applicable when recursive is TRUE. This is the depth when searching value relations recursively. If NULL, all possible recursive relations are returned. Default: 1.

Details: Many fields in **Idf** can be referred by others. For example, the Outside Layer and other fields in Construction class refer to the Name field in Material class and other material related classes. Here it means that the Outside Layer field **refers to** the Name field and the Name field is **referred by** the Outside Layer. In EnergyPlus, there is also a special type of field called Node, which together with Branch, BranchList and other classes define the topography of the HVAC connections. A outlet node of a component can be referred by another component as its inlet node, but can also exist independently, such as zone air node.

\$object_relation() provides a simple interface to get this kind of relation. It takes a single object ID or name and also a relation direction, and returns an IdfRelation object which contains data presenting such relation above. For instance, if model\$object_relation("WALL-1", "ref_to") gives results below:

```
-- Refer to Others -----
Class: <Construction>
\-- Object [ID:2] <WALL-1>
  \-- 2: "WD01";          !- Outside Layer
    v~-----
  \-- Class: <Material>
    \-- Object [ID:1] <WD01>
      \-- 1: "WD01";          !- Name
```

This means that the value "WD01" of Outside Layer in a construction named WALL-1 refers to a material named WD01. All those objects can be further easily extracted using \$objects_in_relation() method described below.

Returns: An IdfRelation object, which is a list of 3 `data.table::data.table()`s named ref_to, ref_by and node. Each `data.table::data.table()` contains 24 columns.

Examples:

```
\dontrun{
# check each layer's reference of a construction named FLOOR
idf$object_relation("floor", "ref_to")
```

```
# check where is this construction being used
idf$object_relation("floor", "ref_by")
}
```

Method `objects_in_relation()`: Extract multiple [IdfObject](#) objects referencing each others.

Usage:

```
Idf$objects_in_relation(
  which,
  direction = c("ref_to", "ref_by", "node"),
  class = NULL,
  recursive = FALSE,
  depth = 1L
)
```

Arguments:

`which` A single integer specifying object ID or a single string specifying object name.

`direction` The relation direction to extract. Should be one of "ref_to", "ref_by" or "node".

`class` A character vector of valid class names in the underlying [Idd](#). It is used to restrict the classes to be returned. If NULL, all possible classes are considered and corresponding [IdfObject](#) objects are returned if relationships are found. Default: NULL.

`recursive` If TRUE, the relation is searched recursively. A simple example of recursive reference: one material named `mat` is referred by a construction named `const`, and `const` is also referred by a surface named `surf`. If `recursive` is TRUE, all relations above will be extracted.

`depth` Only applicable when `recursive` is TRUE. This is the depth when searching value relations recursively. If NULL, all possible recursive relations are returned. Default: 1.

Details: `$objects_in_relation()` returns a named list of [IdfObject](#) objects that have specified relationship with given object. The first element of returned list is always the specified object itself. If that object does not have specified relationship with other objects in specified class, a list that only contains specified object itself is returned.

For instance, assuming that `const` is a valid object name in `Construction` class, `idf$objects_in_relation("const", 'BuildingSurface:Detailed')` will return a named list of an [IdfObject](#) object named `const` and also all other [IdfObject](#) objects in `BuildingSurface:Detailed` class that refer to field values in `const`. Similarly, `idf$objects_in_relation("const", 'Material')` will return a named list of an [IdfObject](#) object named `const` and also all other [IdfObject](#) objects in `Material` class that `const` refers to. This makes it easy to directly extract groups of related objects and then use `$insert()` method or other methods described below to insert them or extract data.

There are lots of recursive references in a model. For instance, a material can be referred by a construction, that construction can be referred by a building surface, and that building surface can be referred by a window on that surface. These objects related recursively can be extracted by setting `recursive` to TRUE.

Returns: An named list of [IdfObject](#) objects.

Examples:

```
\dontrun{
# get a construction named FLOOR and all materials it uses
idf$objects_in_relation("floor", "ref_to")
}
```

```
# get a construction named FLOOR and all surfaces that uses it
idf$objects_in_relation("floor", "ref_by", "BuildingSurface:Detailed")
}
```

Method `search_object()`: Extract multiple [IdfObject](#) objects using regular expression on names.

Usage:

```
Idf$search_object(
  pattern,
  class = NULL,
  ignore.case = FALSE,
  perl = FALSE,
  fixed = FALSE,
  useBytes = FALSE
)
```

Arguments:

`pattern`, `ignore.case`, `perl`, `fixed`, `useBytes` All are directly passed to [base::grepl](#).
`class` A character vector of valid class names in the underlying [Idd](#). It is used to restrict the classes to be returned. If NULL, all possible classes are considered and corresponding [IdfObject](#) objects are returned if `pattern` is met Default: NULL.

Details: `$search_object()` returns a named list of [IdfObject](#) objects whose names meet the given regular expression in specified classes.

Returns: A named list of [IdfObject](#) objects.

Examples:

```
\dontrun{
# get all objects whose names contains "floor"
idf$search_object("floor", ignore.case = TRUE)
}
```

Method `dup()`: Duplicate existing objects.

Usage:

```
Idf$dup(...)
```

Arguments:

`...` Integer vectors of object IDs and character vectors of object names. If input is named, its name will be used as the name of newly created objects.

Details: `$dup()` takes integer vectors of object IDs and character vectors of object names, duplicates objects specified, and returns a list of newly created [IdfObject](#) objects. The names of input are used as new names for created [IdfObjects](#). If input is not named, new names are the names of duplicated objects with a suffix `"_1"`, `"_2"` and etc, depending on how many times that object has been duplicated. Note an error will be issued if trying to assign a new name to an object which belongs to a class that does not have name attribute.

Assigning newly added objects with an existing name in current Idf object is prohibited if current validation level includes object name conflicting checking. For details, please see `level_checks()`.

Returns: A named list of [IdfObject](#) objects.

Examples:

```
\dontrun{
# duplicate an object named "FLOOR"
idf$dup("floor") # New object name 'FLOOR_1' is auto-generated

# duplicate that object again by specifying object ID
idf$dup(16) # New object name 'FLOOR_2' is auto-generated

# duplicate that object two times and giving new names
idf$dup(new_floor = "floor", new_floor2 = 16)

# duplicate that object multiple times using variable inputs
floors_1 <- c(new_floor3 = "floor", new_floor4 = "floor")
floors_2 <- setNames(rep(16, 5), paste0("flr", 1:5))
idf$dup(floors_1, floors_2)
}
```

Method `add()`: Add new objects.

Usage:

```
Idf$add(..., .default = TRUE, .all = FALSE)
```

Arguments:

- `...` Lists of object definitions. Each list should be named with a valid class name. There is a special element `.comment` in each list, which will be used as the comments of newly added object.
- `.default` If TRUE, default values are used for those blank fields if possible. If FALSE, empty fields are kept blank. Default: TRUE.
- `.all` If TRUE, all fields are added. If FALSE, only minimum required fields are added. Default: FALSE.

Details: `$add()` takes new object definitions in list format, adds corresponding objects in specified classes, returns a list of newly added [IdfObject](#) objects. The returned list will be named using newly added object names. Every list should be named using a valid class name. Underscore-style class name is allowed for class name. Names in each list element are treated as field names. Values without names will be inserted according to their position. There is a special element named `.comment` in each list, which will be used as the comments of newly added object.

Empty objects can be added using an empty list, e.g. `idf$add(Building = list())`. All empty fields will be filled with corresponding default value if `.default` is TRUE, leaving other fields as blanks. However, adding blank objects may not be allowed if there are required fields in that class and current validate level includes missing-required-field checking. For what kind of validation components will be performed during adding new objects, please see [level_checks\(\)](#). Field name matching is **case-insensitive**. For convenience, underscore-style field names are also allowed, e.g. `eNd_MoNtH` is equivalent to `End Month`. This behavior is consistent among all methods that take field names as input.

There is no need to give all field values if only specific fields are interested, as long as other fields are not required. For example, to define a new object in `RunPeriod` class, the following is enough (at least for EnergyPlus v8.8):

```
idf$add(
  RunPeriod = list(
    "my run period",
    begin_month = 1, begin_day_of_month = 1,
    end_month = 1, end_day_of_month = 31
  ),
  .default = TRUE
)
```

If not all field names are given, positions of those values without field names are determined after those values with names. E.g. in `idf$add(Construction = list("out_layer", name = "name"))`, "out_layer" will be treated as the value for field Outside Layer in Construction class, since the value for field Name has been specified using explicit field name.

Returns: A named list of `IdfObject` objects.

Examples:

```
\dontrun{
# add a new Building object with all default values
empty <- empty_idf(8.8) # create an empty Idf
empty$add(Building = list())

# add a new Building object with all default values and comments
empty <- empty_idf(8.8) # create an empty Idf
empty$add(Building = list(.comment = c("this is", "a new building")))

# add a new RunPeriod object with all possible fields
empty <- empty_idf(8.8) # create an empty Idf
empty$add(Building = list(), RunPeriod = list("rp", 1, 1, 1, 31), .all = TRUE)

# add objects using variable inputs
empty <- empty_idf(8.8) # create an empty Idf
objs1 <- list(Schedule_Constant = list("const"), Building = list())
rp <- list(RunPeriod = list("rp", 2, 1, 2, 28))
empty$add(objs1, rp)
}
```

Method `set()`: Set values of existing objects.

Usage:

```
Idf$set(..., .default = TRUE, .empty = FALSE)
```

Arguments:

- ... Lists of object definitions. Each list should be named with a valid object name or ID denoted in style `..ID`. There is a special element `.comment` in each list, which will be used as new comments of modified object, overwriting existing comments if any.
- `.default` If TRUE, default values are used for those blank fields if possible. If FALSE, empty fields are kept blank. Default: TRUE.
- `.empty` If TRUE, trailing empty fields are kept. Default: FALSE.

Details: `$set()` takes new field value definitions in list format, sets new values for fields in objects specified, and returns a list of modified `IdfObjects`. The returned list will be named using names of modified objects. Every list in `$set()` should be named with a valid object name. Object ID can also be used but have to be combined with prevailing two periods `..`, e.g. `..10` indicates the object with ID 10. Similar to `$add()`, a special element `.comment` in each list will be used as the **new** comments for modified object, overwriting the old ones. Names in list element are treated as field names.

There is two special syntax in `$set()`, which is inspired by the `data.table` package:

- `class := list(field = value)`: Note the use of `:=` instead of `=`. The main difference is that, unlike `=`, the left hand side of `:=` should be a valid class name in current Idf object. It will set the field of all objects in specified class to specified value.
- `.(object,object) := list(field = value)`: Simimar like above, but note the use of `.()` in the left hand side. You can put multiple object ID or names in `.()`. It will set the field of all specified objects to specified value.

You can delete a field by assigning NULL to it, e.g. `list(fld = NULL)` means to delete the value of field `fld`, in the condition that `.default` is FALSE, `fld` is not a required field and the index of `fld` is larger than the number minimum fields required for that class. If those conditions are not required, `fld` will be left as blank if `.default` is FALSE or filled with default value if `.default` is TRUE.

By default, trailing empty fields that are not required will be removed and only minimum required fields are kept. For example, if `rp` is an object in `RunPeriod` class in an Idf of version 8.8, by default empty field with index larger than 11 will be removed since they are all non-required fields. You can keep the trailing empty fields by setting `.empty` to TRUE.

New fields that currently do not exist in that object can also be set. They will be automatically added on the fly.

Field name matching is **case-insensitive**. For convenience, underscore-style field names are also allowed, e.g. `eNd_MoNtH` is equivalent to `End Month`.

If not all field names are given, positions of those values without field names are determined after those values with names. E.g. in `idf$set(floor = list("out_layer", name = "name"))`, `"out_layer"` will be treated as the value for field `Outside Layer` in an object named `floor`, since the value for field `Name` has been specified using explicit field name.

Returns: A named list of `IdfObject` objects.

Examples:

```
\dontrun{
# modify an object by name (case-insensitive)
idf$set(r13layer = list(roughness = "smooth"))

# modify an object by ID
idf$set(..12 = list(roughness = "rough"))

# overwrite existing object comments
idf$set(r13layer = list(.comment = c("New comment")))

# assign default values to fields
idf$set(r13layer = list(solar_absorptance = NULL), .default = TRUE)

# set field values to blanks
```

```

idf$set(r13layer = list(solar_absorptance = NULL), .default = FALSE)

# set field values to blank and delete trailing fields
idf$set(r13layer = list(visible_absorptance = NULL), .default = FALSE)

# set field values to blank and keep blank fields
idf$set(r13layer = list(visible_absorptance = NULL), .default = FALSE, .empty = TRUE)

# set all fields in one class
idf$set(Material_NoMass := list(visible_absorptance = 0.9))

# set multiple objects in one class
idf$set.(("r13layer", "r31layer") := list(solar_absorptance = 0.8))
# above is equivalent to
idf$set(r13layer = list(solar_absorptance = 0.8),
        r31layer = list(solar_absorptance = 0.8)
)

# use variable input
sets <- list(r13layer = list(roughness = "smooth"))
idf$set(sets)
}

```

Method del(): Delete existing objects

Usage:

```

Idf$del(
  ...,
  .ref_by = FALSE,
  .ref_to = FALSE,
  .recursive = FALSE,
  .force = FALSE
)

```

Arguments:

- ... integer vectors of object IDs and character vectors of object names in current Idf object.
- .ref_by If TRUE, objects whose fields refer to input objects will also be deleted. Default: FALSE.
- .ref_to If TRUE, objects whose fields are referred by input objects will also be deleted. Default: FALSE.
- .recursive If TRUE, relation searching is performed recursively, in case that objects whose fields refer to target object are also referred by another object, and also objects whose fields are referred by target object are also referred by another object. Default: FALSE.
- .force If TRUE, objects are deleted even if they are referred by other objects.

Details: \$del() takes integer vectors of object IDs and character vectors of object names, and deletes objects specified.

If current [validate level](#) includes reference checking, objects will not be allowed to be deleted if they are referred by other objects. For example, an error will be issued if you want to delete

one material that is referred by other constructions, because doing so will result in invalid field value references. You may bypass this if you really want to by setting `.force` to `TRUE`.

When `.ref_by` or `.ref_to` is `TRUE`, objects will be deleted only when they have and only have relation with input objects but not any other objects. For example, a construction `const` consist of 4 different materials. If `.ref_to` is `TRUE`, that 4 materials will only be deleted when they are only used in `const`, but not used in any other objects.

There are recursively reference relations in `Idf` object. For example, one material's name is referenced by one construction, and that construction's name can be referred by another surface. You can delete all of them by setting `.recursive` to `TRUE`.

If `.ref_by` is `TRUE`, objects whose fields refer to input objects will also be deleted.

If `.ref_to` is `TRUE`, objects whose fields are referred by input objects will also be deleted.

Returns: The modified `Idf` object itself, invisibly.

Examples:

```
\dontrun{
# delete objects using names
idf$object("Fraction") # ScheduleTypeLimits
idf$del("Fraction")

# delete objects using IDs
idf$objects(c(39, 40)) # Output:Variable
idf$del(39, 40)

# cannot delete objects that are referred by others
level_checks()$reference # reference-checking is enable by default
idf$del("r13layer") # error

# force to delete objects even they are referred by others
idf$del("r13layer", .force = TRUE)

# delete objects and also objects that refer to them
idf$del("r31layer", .ref_by = TRUE) # Construction 'ROOF31' will be kept

# delete objects and also objects that they refer to
idf$del("extlights", .ref_to = TRUE) # Schedule 'AlwaysOn' will be kept

# delete objects and also other objects that refer to them recursively
idf$del("roof31", .ref_by = TRUE, .recursive = TRUE)

# delete objects using variable inputs
ids <- idf$object_id("Output:Variable", simplify = TRUE)
idf$del(ids)
}
```

Method `rename()`: Rename existing objects

Usage:

```
Idf$rename(...)
```

Arguments:

... Integer vectors of valid object IDs and character vectors of valid object names in current Idf object. Each element should be named. Names of input vectors are used as the new object names

Details: \$rename() takes named character vectors of object names and named integer vectors of object IDs, renames specified objects to names of input vectors and returns a list of renamed [IdfObjects](#). The returned list will be named using names of modified objects. An error will be issued if trying to "rename" an object which does not have name attribute. When renaming an object that is referred by other objects, corresponding fields that refer to that object's name will also be changed accordingly.

Returns: A named list of renamed [IdfObject](#) objects.

Examples:

```
\dontrun{
idf$objects(c("on/off", "test 352a"))
idf$rename(on_off = "on/off", test_352a = 51)
}
```

Method insert(): Insert new objects from [IdfObjects](#)*Usage:*

```
Idf$insert(..., .unique = TRUE, .empty = FALSE)
```

Arguments:

... [IdfObjects](#) or lists of [IdfObjects](#) from same version as current Idf object.
 .unique If there are duplications in input [IdfObjects](#) or there is same object in current Idf object, duplications in input are removed. Default: TRUE.
 .empty If TRUE, trailing empty fields are kept. Default: FALSE.

Details: \$insert() takes [IdfObjects](#) or lists of [IdfObjects](#) as input, inserts them into current Idf objects, and returns a list of inserted [IdfObjects](#). The returned list will be named using names of inserted objects.

\$insert() is quite useful to insert objects from other Idf objects. However, you cannot insert an [IdfObject](#) which comes from a different version than current Idf object.

\$insert() will skip [IdfObjects](#) that have exactly same fields in current Idf object. If input [IdfObject](#) has the same name as one [IdfObject](#) in current Idf object but field values are not equal, an error will be issued if current [validate level](#) includes conflicted-name checking.

By default, trailing empty fields that are not required will be removed and only minimum required fields are kept. You can keep the trailing empty fields by setting .empty to TRUE.

Returns: A named list of inserted [IdfObject](#) objects.

Examples:

```
\dontrun{
# insert all material from another IDF
path_idf2 <- file.path(eplus_config(8.8)$dir, "ExampleFiles/5ZoneTDV.idf")
idf2 <- Idf$new(path_idf2)
idf$insert(idf2$Material)
```

```
# insert objects from same Idf is equivalent to using Idf$dup()
idf$insert(idf$SizingPeriod_DesignDay)
}
```

Method load(): Load new objects from characters or data.frames

Usage:

```
Idf$load(..., .unique = TRUE, .default = TRUE, .empty = FALSE)
```

Arguments:

- ... Character vectors or data.frames of object definitions.
- .unique If TRUE, and there are duplications in input **IdfObjects** or there is same object in current Idf object, duplications in input are removed. Default: TRUE.
- .default If TRUE, default values are filled for those blank fields if possible. Default: TRUE.
- .empty If TRUE, trailing empty fields are kept. Default: FALSE.

Details: \$load() is similar to **\$insert()**, except it takes directly character vectors or data.frames as **IdfObject** definitions, insert corresponding objects into current Idf object and returns a named list of newly added **IdfObjects**. The returned list will be named using names of added objects. This makes it easy to create objects using the output from **\$to_string()** and **\$to_table()** method from **Idd**, **IddObject**, also from **Idf**, and **IdfObject**, class.

For object definitions in character vector format, they follow the same rules as a normal IDF file:

- Each object starts with a class name and a comma (,);
- Separates each values with a comma (,);
- Ends an object with a semicolon (;) for the last value.

Each character vector can contain:

- One single object, e.g. c("Building, ", "MyBuilding;"), or "Building, MyBuilding;".
- Multiple objects, e.g. c("Building,MyBuilding; ", "SimulationControl,Yes").

You can also provide an option header to indicate if input objects are presented in IP units, using **!-Option ViewInIPunits**. If this header does not exist, then all values are treated as in SI units.

For object definitions in data.frame format, it is highly recommended to use **\$to_table()** method in **Idd**, **Idd**, **IddObject**, **IddObject**, **Idf**, and **IdfObject**, class to create an acceptable data.frame template. A valid definition requires at least three columns described below. Note that column order does not matter.

- class:Character type. Valid class names in the underlying **Idd** object.
- index:Integer type. Valid field indices for each class.
- value:Character type or list type. Value for each field to be added.
 - If character type, usually when **string_value** is TRUE in method **\$to_table()** in **Idf** and **IdfObject** class. Note that each value should be given as a string even if the corresponding field is a numeric type.
 - If list type, usually when **string_value** is set to FALSE in method **\$to_table()** in **Idf** and **IdfObject** class. Each value should have the right type as the corresponding field definition. Otherwise, errors will be issued if current **validation level** includes invalid-type checking.
- id: **Optional**. Integer type. If input data.frame includes multiple object definitions in a same class, values in id column will be used to distinguish each definition. If id column

does not exist, it assumes that each definition is separated by class column and will issue an error if there is any duplication in the index column.

Note that `$load()` assumes all definitions are from the same version as current Idf object. If input definition is from different version, parsing error may occur.

By default, trailing empty fields that are not required will be removed and only minimum required fields are kept. You can keep the trailing empty fields by setting `.empty` to `TRUE`.

Returns: A named list of loaded `IdfObject` objects.

Examples:

```
\dontrun{
# load objects from character vectors
idf$load(
  c("Material,",
    "  mat,                !- Name",
    "  MediumSmooth,       !- Roughness",
    "  0.667,               !- Thickness {m}",
    "  0.115,               !- Conductivity {W/m-K}",
    "  513,                 !- Density {kg/m3}",
    "  1381;                !- Specific Heat {J/kg-K}"),

  "Construction, const, mat;"
)

# load objects from data.frame definitions
dt <- idf$to_table(class = "Material")
dt[field == "Name", value := paste(value, 1)]
dt[field == "Thickness", value := "0.5"]
idf$load(dt)

# by default, duplications are removed
idf$load(idf$to_table(class = "Material"))

# keep empty fields as they are
idf$load("Material, mat1, smooth, 0.5, 0.2, 500, 1000,, , 0.5;", .default = FALSE)

# keep trailing empty fields
idf$load("Material, mat2, smooth, 0.5, 0.2, 500, 1000,, ,;",
  .default = FALSE, .empty = TRUE
)
}
```

Method `update()`: Update existing object values from characters or data.frames

Usage:

```
Idf$update(..., .default = TRUE, .empty = FALSE)
```

Arguments:

... Character vectors or data.frames of object definitions.

`.default` If `TRUE`, default values are filled for those blank fields if possible. Default: `TRUE`.

.empty If TRUE, trailing empty fields are kept. Default: FALSE.

Details: \$update() is similar to \$set(), except it takes directly character vectors or data.frames as IdfObject definitions, updates new values for fields in objects specified, and returns a named list of modified IdfObjects. The returned list will be named using names of modified objects. This makes it easy to update object values using the output from \$to_string() and \$to_table method from Idf, and IdfObject, class.

The format of object definitions is similar to \$load().

For object definitions in character vector format, object names are used to locate which objects to update. Objects that have name attribute should have valid names. This means that there is no way to update object names using character vector format, but this can be achieved using data.frame format as it uses object IDs instead of object names to locate objects. The format of acceptable characters follows the same rules as a normal IDF file:

- Each object starts with a class name and a comma (,);
- Separates each values with a comma (,);
- Ends an object with a semicolon (;) for the last value.

Each character vector can contain:

- One single object, e.g. c("Building, ", "MyBuilding;"), or "Building, MyBuilding;".
- Multiple objects, e.g. c("Building,MyBuilding; ", "SimulationControl,Yes").

You can also provide an option header to indicate if input objects are presented in IP units, using !-Option ViewInIPunits. If this header does not exist, then all values are treated as in SI units.

For object definitions in data.frame format, it is highly recommended to use \$to_table() method in Idf, and IdfObject, class to create an acceptable data.frame template. A valid definition requires three columns described below. Note that column order does not matter.

- id: Integer type. Valid IDs of objects to update.
- index: Integer type. Valid field indices for each object.
- value: Character type or list type. Value for each field to be added.
 - If character type, usually when string_value is TRUE in method \$to_table() in Idf and IdfObject class. Note that each value should be given as a string even if the corresponding field is a numeric type.
 - If list type, usually when string_value is set to FALSE in method \$to_table() in Idf and IdfObject class. Each value should have the right type as the corresponding field definition. Otherwise, errors will be issued if current validation level includes invalid-type checking.

Note that \$update() assumes all definitions are from the same version as current Idf object. If input definition is from different version, parsing error may occur.

By default, trailing empty fields that are not required will be removed and only minimum required fields are kept. You can keep the trailing empty fields by setting .empty to TRUE.

Returns: A named list of updated IdfObject objects.

Examples:

```
\dontrun{
# update objects from string definitions:
str <- idf$to_string("zone one", header = FALSE, format = "new_top")
str[8] <- "2," # Multiplier
idf$update(str)
```

```
# update objects from data.frame definitions:
dt <- idf$to_table("zone one")
dt[field == "Multiplier", value := "1"]
idf$update(dt)
}
```

Method `paste()`: Paste new objects from IDF Editor

Usage:

```
Idf$paste(in_ip = FALSE, ver = NULL, unique = TRUE, empty = FALSE)
```

Arguments:

`in_ip` Set to TRUE if the IDF file is open with Inch-Pound view option toggled. Numeric values will automatically converted to SI units if necessary. Default: FALSE.

`ver` The version of IDF file open by IDF Editor, e.g. 8.6, "8.8.0". If NULL, assume that the file has the same version as current Idf object. Default: NULL.

`unique` If TRUE, and there are duplications in copied objects from IDF Editor or there is same object in current Idf, duplications in input are removed. Default: TRUE.

`empty` If TRUE, trailing empty fields are kept. Default: FALSE.

Details: `$paste()` reads the contents (from clipboard) of copied objects from IDF Editor (after hitting Copy Obj button), inserts corresponding objects into current Idf object and returns a named list of newly added [IdfObjects](#). The returned list will be named using names of added objects. As IDF Editor is only available on Windows platform, `$paste()` only works on Windows too.

There is no version data copied to the clipboard when copying objects in IDF Editor. `$paste()` assumes the file open in IDF Editor has the same version as current Idf object. This may not be always true. Please check the version before running `$paste()`, or explicitly specify the version of file opened by IDF Editor using `ver` parameter. Parsing error may occur if there is a version mismatch.

By default, trailing empty fields that are not required will be removed and only minimum required fields are kept. You can keep the trailing empty fields by setting `.empty` to TRUE.

Returns: A named list of loaded [IdfObject](#) objects.

Method `search_value()`: Search objects by field values using regular expression

Usage:

```
Idf$search_value(
  pattern,
  class = NULL,
  ignore.case = FALSE,
  perl = FALSE,
  fixed = FALSE,
  useBytes = FALSE
)
```

Arguments:

`pattern`, `ignore.case`, `perl`, `fixed`, `useBytes` All of them are directly passed to [base::grep](#) and [base::gsub](#).

class A character vector of invalid class names in current Idf object to search for values. If NULL, all classes are used. Default: NULL.

Details: \$search_value() returns a list of [IdfObjects](#) that contain values which match the given pattern. If no matched found, NULL is returned invisibly. The returned list will be named using names of matched objects.

Note that during matching, all values are treated as characters, including numeric values.

Returns: A named list of [IdfObject](#) objects.

Examples:

```
\dontrun{
# search values that contains "floor"
idf$search_value("floor", ignore.case = TRUE)

# search values that contains "floor" in class Construction
idf$search_value("floor", "Construction", ignore.case = TRUE)
}
```

Method `replace_value()`: Replace object field values using regular expression

Usage:

```
Idf$replace_value(
  pattern,
  replacement,
  class = NULL,
  ignore.case = FALSE,
  perl = FALSE,
  fixed = FALSE,
  useBytes = FALSE
)
```

Arguments:

pattern, replacement, ignore.case, perl, fixed, useBytes All of them are directly passed to [base::grepl](#) and [base::gsub](#).

class A character vector of invalid class names in current Idf object to search for values. If NULL, all classes are used. Default: NULL.

Details: \$replace_value() returns a list of [IdfObjects](#) whose values have been replaced using given pattern. If no matched found, NULL is returned invisibly. The returned list will be named using names of matched objects.

Note that during matching, all values are treated as characters, including numeric values.

Modifying object values using regular expression is not recommended. Consider to use [\\$set\(\)](#) and [\\$update\(\)](#) if possible. [Validation](#) rules also apply during replacing.

Returns: A named list of [IdfObject](#) objects.

Examples:

```
\dontrun{
# search values that contains "win" and replace them with "windows"
idf$replace_value("win", "windows")
}
```

Method `validate()`: Check possible object field value errors

Usage:

```
Idf$validate(level = eplusr_option("validate_level"))
```

Arguments:

`level` One of "none", "draft", "final" or a list of 10 elements with same format as `custom_validate()` output.

Details: `$validate()` checks if there are errors in current Idf object under specified validation level and returns an `IdfValidity` object. `$validate()` is useful to help avoid some common errors before running the model. By default, validation is performed when calling all methods that modify objects, e.g. `$dup()`, `$add()`, `$set()`, `$del()`, and etc.

In total, there are 10 different validate checking components:

- `required_object`: Check if required objects are missing in current Idf.
- `unique_object`: Check if there are multiple objects in one unique-object class. An unique-object class means that there should be at most only one object existing in that class.
- `unique_name`: Check if all objects in each class have unique names.
- `extensible`: Check if all fields in an extensible group have values. An extensible group is a set of fields that should be treated as a whole, such like the X, Y and Z vertices of a building surfaces. An extensible group should be added or deleted together. `extensible` component checks if there are some, but not all, fields in an extensible group are empty.
- `required_field`: Check if all required fields have values.
- `auto_field`: Check if all fields filled with value "Autosize" and "Autocalculate" are actual autosizable and autocalculatable fields or not.
- `type`: Check if all fields have value types complied with their definitions, i.e. character, numeric and integer fields should be filled with corresponding type of values.
- `choice`: Check if all choice fields are filled with valid choice values.
- `range`: Check if all numeric fields have values within prescribed ranges.
- `reference`: Check if all fields whose values refer to other fields are valid.

The `level` argument controls what checkings should be performed. `level` here is just a list of 10 element which specify the toggle status of each component. You can use helper `custom_validate()` to get that list and pass it directly to `level`.

There are 3 predefined validate level that indicates different combinations of checking components, i.e. `none`, `draft` and `final`. Basically, `none` level just does not perform any checkings; `draft` includes 5 components, i.e. `auto_field`, `type`, `unique_name`, `choice` and `range`; and `final` level includes all 10 components. You can always get what components each level contains using `level_checks()`. By default, the result from `eplusr_option("validate_level")` is passed to `level`. If not set, `final` level is used.

Underneath, an `IdfValidity` object which `$validate()` returns is a list of 13 element as shown below. Each element or several elements represents the results from a single validation checking component.

- `missing_object`: Result of `required_object` checking.
- `duplicate_object`: Result of `unique_object` checking.
- `conflict_name`: Result of `unique_name` checking.
- `incomplete_extensible`: Result of `extensible` checking.
- `missing_value`: Result of `required_field` checking.
- `invalid_autosize`: Result of `auto_field` checking for invalid Autosize field values.

- `invalid_autocalculate`: Result of `auto_field` checking for invalid Autocalculate field values.
- `invalid_character`: Result of type checking for invalid character field values.
- `invalid_numeric`: Result of type checking for invalid numeric field values.
- `invalid_integer`: Result of type checking for invalid integer field values.
- `invalid_choice`: Result of choice checking.
- `invalid_range`: Result of range checking.
- `invalid_reference`: Result of reference checking.

Except `missing_object`, which is a character vector of class names that are missing, all other elements are [data.table](#) with 9 columns containing data of invalid field values:

- `object_id`: IDs of objects that contain invalid values
- `object_name`: names of objects that contain invalid values
- `class_id`: indexes of classes that invalid objects belong to
- `class_name`: names of classes that invalid objects belong to
- `field_id`: indexes (at Idd level) of object fields that are invalid
- `field_index`: indexes of object fields in corresponding that are invalid
- `field_name`: names (without units) of object fields that are invalid
- `units`: SI units of object fields that are invalid
- `ip_units`: IP units of object fields that are invalid
- `type_enum`: An integer vector indicates types of invalid fields
- `value_id`: indexes (at Idf level) of object field values that are invalid
- `value_chr`: values (converted to characters) of object fields that are invalid
- `value_num`: values (converted to numbers in SI units) of object fields that are invalid

Knowing the internal structure of `IdfValidity`, it is easy to extract invalid `IdfObjects` you interested in. For example, you can get all IDs of objects that contain invalid value references using `model$validate()$invalid_reference$object_id`. Then using `$set()` method to correct them.

Different validate result examples are shown below:

- No error is found:

```
v No error found.
```

Above result shows that there is no error found after conducting all validate checks in specified validate level.

- Errors are found:

```
x [2] Errors found during validation.
```

```
=====
```

```
-- [2] Invalid Autocalculate Field -----
Fields below cannot be `autocalculate`:
```

```
Class: <AirTerminal:SingleDuct:VAV:Reheat>
\~ Object [ID:176] <SPACE5-1 VAV Reheat>
+- 17: AUTOCALCULATE, !- Maximum Flow per Zone Floor Area During Reheat {m3/s-m2}
  \~ 18: AUTOCALCULATE; !- Maximum Flow Fraction During Reheat
```

Above result shows that after all validate components performed under current validate level, 2 invalid field values are found. All of them are in a object named SPACE5-1 VAV Reheat with ID 176. They are invalid because those two fields do not have an autocalculatable attribute but are given AUTOCALCULATE value. Knowing this info, one simple way to fix the error is to correct those two fields by doing:

```
idf$set(..176 =
  list(`Maximum Flow per Zone Floor Area During Reheat` = "autosize",
       `Maximum Flow Fraction During Reheat` = "autosize"
  )
)
```

Returns: An IdfValidity object.

Examples:

```
\dontrun{
idf$validate()

# check at predefined validate level
idf$validate("none")
idf$validate("draft")
idf$validate("final")

# custom validate checking components
idf$validate(custom_validate(auto_field = TRUE, choice = TRUE))
}
```

Method `is_valid()`: Check if there is any error in current Idf

Usage:

```
Idf$is_valid(level = eplusr_option("validate_level"))
```

Arguments:

level One of "none", "draft", "final" or a list of 10 elements with same format as [custom_validate\(\)](#) output.

Details: `$is_valid()` checks if there are errors in current Idf object under specified validation level and returns TRUE or FALSE accordingly. For detailed description on validate checking, see [\\$validate\(\)](#) documentation above.

Returns: A single logical value of TRUE or FALSE.

Examples:

```
\dontrun{
idf$is_valid()

# check at predefined validate level
idf$is_valid("none")
idf$is_valid("draft")
idf$is_valid("final")

# custom validate checking components
```

```
idf$is_valid(custom_validate(auto_field = TRUE, choice = TRUE))
}
```

Method `to_string()`: Format Idf as a character vector

Usage:

```
Idf$to_string(
  which = NULL,
  class = NULL,
  comment = TRUE,
  header = TRUE,
  format = eplusr_option("save_format"),
  leading = 4L,
  sep_at = 29L
)
```

Arguments:

`which` Either an integer vector of valid object IDs or a character vector of valid object names.

If NULL, the whole Idf object is converted. Default: NULL.

`class` A character vector of class names. If NULL, all classed in current Idf object is converted.

Default: NULL.

`comment` If FALSE, all comments will not be included. Default: TRUE.

`header` If FALSE, the header will not be included. Default: TRUE.

`format` Specific format used when formatting. Should be one of "asis", "sorted", "new_top", and "new_bot".

- If "asis", Idf object will be formatted in the same way as it was when first read. If Idf object does not contain any format saving option, which is typically the case when the model was not saved using eplusr or IDFEditor, "sorted" will be used.
- "sorted", "new_top" and "new_bot" are the same as the save options "Sorted", "Original with New at Top", and "Original with New at Bottom" in IDFEditor. Default: `eplusr_option("save_format")`

`leading` Leading spaces added to each field. Default: 4L.

`sep_at` The character width to separate value string and field string. Default: 29L which is the same as IDF Editor.

Details: `$to_string()` returns the text format of parts or whole Idf object.

Returns: A character vector.

Examples:

```
\dontrun{
# get text format of the whole Idf
head(idf$to_string())

# get text format of the whole Idf, excluding the header and all comments
head(idf$to_string(comment = FALSE, header = FALSE))

# get text format of all objects in class Material
head(idf$to_string(class = "Material", comment = FALSE, header = FALSE))
}
```

```
# get text format of some objects
head(idf$to_string(c("floor", "zone one")))

# tweak output formatting
head(idf$to_string("floor", leading = 0, sep_at = 0))
}
```

Method to_table(): Format Idf as a data.frame

Usage:

```
Idf$to_table(
  which = NULL,
  class = NULL,
  string_value = TRUE,
  unit = FALSE,
  wide = FALSE,
  align = FALSE,
  all = FALSE,
  group_ext = c("none", "group", "index")
)
```

Arguments:

which Either an integer vector of valid object IDs or a character vector of valid object names.

If NULL, the whole Idf object is converted. Default: NULL.

class A character vector of class names. If NULL, all classed in current Idf object is converted.

Default: NULL.

string_value If TRUE, all field values are returned as character. If FALSE, value column in returned [data.table](#) is a list column with each value stored as corresponding type. Note that if the value of numeric field is set to "Autosize" or "Autocalculate", it is left as it is, leaving the returned type being a string instead of a number. Default: TRUE.

unit Only applicable when string_value is FALSE. If TRUE, values of numeric fields are assigned with units using [units::set_units\(\)](#) if applicable. Default: FALSE.

wide Only applicable if target objects belong to a same class. If TRUE, a wide table will be returned, i.e. first three columns are always id, name and class, and then every field in a separate column. Note that this requires all objects specified must from the same class. Default: FALSE.

align If TRUE, all objects in the same class will have the same field number. The number of fields is the same as the object that have the most fields among objects specified. Default: FALSE.

all If TRUE, all available fields defined in IDD for the class that objects belong to will be returned. Default: FALSE.

group_ext Should be one of "none", "group" or "index". If not "none", value column in returned [data.table::data.table\(\)](#) will be converted into a list. If "group", values from extensible fields will be grouped by the extensible group they belong to. For example, coordinate values of each vertex in class BuildingSurface:Detailed will be put into a list. If "index", values from extensible fields will be grouped by the extensible field indice they belong to. For example, coordinate values of all x coordinates will be put into a list. If "none", nothing special will be done. Default: "none".

Details: `$to_table()` returns a [data.table](#) that contains core data of specified objects. The returned [data.table](#) has 6 columns:

- `id`: Integer type. Object IDs.
- `name`: Character type. Object names.
- `class`: Character type. Current class name.
- `index`: Integer type. Field indexes.
- `field`: Character type. Field names.
- `value`: Character type if `string_value` is TRUE or list type if `string_value` is FALSE or `group_ext` is not "none". Field values.

Note that when `group_ext` is not "none", `index` and `field` values will not match the original field indices and names. In this case, `index` will only indicate the indices of sequences. For `field` column, specifically:

- When `group_ext` is "group", each field name in a extensible group will be abbreviated using [abbreviate\(\)](#) with `minlength` being 10L and all abbreviated names will be separated by | and combined together. For example, field names in the extensible group (Vertex 1 X-coordinate, Vertex 1 Y-coordinate, Vertex 1 Z-coordinate) in class `BuildiBuildingSurface:Detailed` will be merged into one name `Vrtx1X-crd|Vrtx1Y-crd|Vrtx1Z-crd`.
- When `group_ext` is "index", the extensible group indicator in field names will be removed. Take the same example as above, the resulting field names will be Vertex X-coordinate, Vertex Y-coordinate, and Vertex Z-coordinate.

Returns: A [data.table](#) with 6 columns (if `wide` is FALSE) or at least 6 columns (if `wide` is TRUE).

Examples:

```
\dontrun{
# extract whole Idf data
idf$to_table()

# extract all data from class Material
idf$to_table(class = "Material")

# extract multiple object data
idf$to_table(c("FLOOR", "ZONE ONE"))

# keep value types and put actual values into a list column
idf$to_table(c("FLOOR", "ZONE ONE"), string_value = FALSE)$value

# add the unit to each value
idf$to_table(c("FLOOR", "ZONE ONE"), string_value = FALSE, unit = TRUE)

# get all possible fields
idf$to_table("ZONE ONE", all = TRUE)

# make sure all objects in same class have the same number of fields
idf$to_table(class = "Construction", align = TRUE)

# get a wide table with string values
idf$to_table(class = "Construction", wide = TRUE)
```

```

# get a wide table with actual values
idf$to_table(class = "OtherEquipment", wide = TRUE, string_value = FALSE)

# group extensible by extensible group number
idf$to_table(class = "BuildingSurface:Detailed", group_ext = "group")

# group extensible by extensible group number and convert into a wide table
idf$to_table(class = "BuildingSurface:Detailed", group_ext = "group", wide = TRUE)

# group extensible by extensible field index
idf$to_table(class = "BuildingSurface:Detailed", group_ext = "index")

# group extensible by extensible field index and convert into a wide table
idf$to_table(class = "BuildingSurface:Detailed", group_ext = "index", wide = TRUE)

# when grouping extensible, 'string_value' and 'unit' still take effect
idf$to_table(class = "BuildingSurface:Detailed", group_ext = "index",
             wide = TRUE, string_value = FALSE, unit = TRUE
)
}

```

Method `is_unsaved()`: Check if there are unsaved changes in current Idf

Usage:

```
Idf$is_unsaved()
```

Details: `$is_unsaved()` returns TRUE if there are modifications on the model since it was read or since last time it was saved, and returns FALSE otherwise.

Returns: A single logical value of TRUE or FALSE.

Examples:

```

\dontrun{
idf$is_unsaved()
}

```

Method `save()`: Save Idf object as an IDF file

Usage:

```

Idf$save(
  path = NULL,
  format = eplusr_option("save_format"),
  overwrite = FALSE,
  copy_external = TRUE
)

```

Arguments:

`path` A path where to save the IDF file. If NULL, the path of the Idf itself, i.e. `$path()`, will be used.

format Specific format used when formatting. Should be one of "asis", "sorted", "new_top", and "new_bot".

- If "asis", Idf object will be formatted in the same way as it was when first read. If Idf object does not contain any format saving option, which is typically the case when the model was not saved using eplusr or IDFEditor, "sorted" will be used.
- "sorted", "new_top" and "new_bot" are the same as the save options "Sorted", "Original with New at Top", and "Original with New at Bottom" in IDFEditor. Default: eplusr_option("save_format")

overwrite Whether to overwrite the file if it already exists. Default: FALSE.

copy_external If TRUE, the external files that current Idf object depends on will also be copied into the same directory. The values of file paths in the Idf will be changed into relative path automatically. This makes it possible to create fully reproducible simulation conditions. Currently, only Schedule:File class is supported. Default: FALSE.

Details: \$save() formats current Idf object, saves it as an IDF file and returns the path of saved file invisibly. After saving, \$path() will also be updated to return the path of saved file.

Returns: A length-one character vector, invisibly.

Examples:

```
\dontrun{
# save Idf as a new file
idf$save(tempfile(fileext = ".idf"))

# save and overwrite current file
idf$save(overwrite = TRUE)

# save the model with newly created and modified objects at the top
idf$save(overwrite = TRUE, format = "new_top")

# save the model to a new file and copy all external csv files used in
# "Schedule:File" class into the same folder
idf$save(path = file.path(tempdir(), "test1.idf"), copy_external = TRUE)
}
```

Method run(): Run simulation using EnergyPlus

Usage:

```
Idf$run(
  weather,
  dir = NULL,
  wait = TRUE,
  force = FALSE,
  copy_external = FALSE,
  echo = wait
)
```

Arguments:

weather A path to an .epw file or an [Epw](#) object. weather can also be NULL which will force design-day-only simulation. Note that this needs at least one Sizing:DesignDay object exists in the Idf.

- `dir` The directory to save the simulation results. If NULL, the folder of `Idf` path will be used. Default: NULL.
- `wait` Whether to wait until the simulation completes and print the standard output and error of EnergyPlus. If FALSE, the simulation will run in the background. Default is TRUE.
- `force` Only applicable when the last simulation runs with `wait` equals to FALSE and is still running. If TRUE, current running job is forced to stop and a new one will start. Default: FALSE.
- `copy_external` If TRUE, the external files that current `Idf` object depends on will also be copied into the simulation output directory. The values of file paths in the `Idf` will be changed automatically. Currently, only `Schedule:File` class is supported. This ensures that the output directory will have all files needed for the model to run. Default is FALSE.
- `echo` Only applicable when `wait` is TRUE. Whether to show standard output and error from EnergyPlus. Default: same as `wait`.

Details: `$run()` calls corresponding version of EnergyPlus to run the current `Idf` object together with specified weather. The model and the weather used will be copied into the output directory. An `EplusJob` object is returned which provides detailed info of the simulation and methods to collect simulation results. Please see `EplusJob` for details.

`eplusr` uses the EnergyPlus command line interface which was introduced since EnergyPlus 8.3.0. So `$run()` only supports models with version no lower than 8.3.0.

When calling `$run()`, `eplusr` will do steps below to make sure the output collecting methods work as expected. Please note that this may result in an IDF file that may not be exactly same as your current `Idf` object.

- `eplusr` uses EnergyPlus SQL output for extracting simulation results. In order to do so, an object in `Output:SQLite` class with `Option Type` value being `SimpleAndTabular` will be automatically created if it does not exists.
- In order to make sure `.rdd` (Report Data Dictionary) and `.mdd` (Meter Data Dictionary) files are created during simulation, an object in `Output:VariableDictionary` class with `Key Field` value being `IDF` will be automatically created if it does not exists.

Returns: An `EplusJob` object of current simulation.

Examples:

```
\dontrun{
idf <- Idf$new(path_idf)
# save the model to tempdir()
idf$save(file.path(tempdir(), "test_run.idf"))

# use the first epw file in "WeatherData" folder in EnergyPlus v8.8
# installation path
epw <- list.files(file.path(eplus_config(8.8)$dir, "WeatherData"),
  pattern = "\\*.epw$", full.names = TRUE)[1]

# if `dir` is NULL, the directory of IDF file will be used as simulation
# output directory
job <- idf$run(epw, dir = NULL)

# run simulation in the background
idf$run(epw, dir = tempdir(), wait = FALSE)
```

```

# copy all external files into the directory run simulation
idf$run(epw, dir = tempdir(), copy_external = TRUE)

# check for simulation errors
job$errors()

# get simulation status
job$status()

# get output directory
job$output_dir()

# re-run the simulation
job$run()

# get simulation results
job$report_data()
}

```

Method last_job(): Get the last simulation job

Usage:

```
Idf$last_job()
```

Details: \$last_job() returns the last [EplusJob](#) object that was created using [\\$run\(\)](#). If the Idf hasn't been run yet, NULL is returned.

Returns: NULL or an [EplusJob](#) object.

Examples:

```

\dontrun{
idf$last_job()
}

```

Method print(): Print Idf object

Usage:

```
Idf$print(zoom = "class", order = TRUE)
```

Arguments:

zoom Control how detailed of the Idf object should be printed. Should be one of "group", "class", "object" and "field". Default: "group".

- "group": all group names current existing are shown with prevailing square bracket showing how many **C**lasses existing in that group.
- "class": all class names are shown with prevailing square bracket showing how many **O**bjects existing in that class, together with parent group name of each class.
- "object": all object IDs and names are shown, together with parent class name of each object.

- "field": all object IDs and names, field names and values are shown, together with parent class name of each object.

order Only applicable when zoom is "object" or "field". If TRUE, objects are shown as the same order in the IDF. If FALSE, objects are grouped and ordered by classes. Default: TRUE.

Details: \$print() prints the Idf object according to different detail level specified using the zoom argument.

With the default zoom level object, contents of the Idf object is printed in a similar style as you see in IDF Editor, with additional heading lines showing Path, Version of the Idf object. Class names of objects are ordered by group and the number of objects in classes are shown in square bracket.

Returns: The Idf object itself, invisibly.

Examples:

```
\dontrun{
idf$print("group")
idf$print("class")
idf$print("object")
idf$print("field")

# order objects by there classes
idf$print("object", order = FALSE)
idf$print("field", order = FALSE)
}
```

Method clone(): The objects of this class are cloneable with this method.

Usage:

```
Idf$clone(deep = TRUE)
```

Arguments:

deep Whether to make a deep clone.

idf$to_table(class = "BuildingSurface:Detailed", group_ext = "group")

# group extensible by extensible group number and convert into a wide table
idf$to_table(class = "BuildingSurface:Detailed", group_ext = "group", wide = TRUE)

# group extensible by extensible field index
idf$to_table(class = "BuildingSurface:Detailed", group_ext = "index")

# group extensible by extensible field index and convert into a wide table
idf$to_table(class = "BuildingSurface:Detailed", group_ext = "index", wide = TRUE)

# when grouping extensible, 'string_value' and 'unit' still take effect
idf$to_table(class = "BuildingSurface:Detailed", group_ext = "index",
             wide = TRUE, string_value = FALSE, unit = TRUE
)

IdfObject

Create and Modify an EnergyPlus Object

Description

IdfObject is an abstraction of a single object in an [Idf](#). It provides more detail methods to modify object values and comments. An IdfObject object can also be created using function [idf_object\(\)](#) or from methods of a parent [Idf](#) object, using [\\$object\(\)](#), [\\$objects_in_class\(\)](#) and equivalent.

Methods

Public methods:

- [IdfObject\\$new\(\)](#)
- [IdfObject\\$version\(\)](#)
- [IdfObject\\$parent\(\)](#)
- [IdfObject\\$id\(\)](#)
- [IdfObject\\$name\(\)](#)
- [IdfObject\\$group_name\(\)](#)
- [IdfObject\\$class_name\(\)](#)

- IdfObject\$definition()
- IdfObject\$comment()
- IdfObject\$value()
- IdfObject\$set()
- IdfObject\$value_possible()
- IdfObject\$validate()
- IdfObject\$is_valid()
- IdfObject\$value_relation()
- IdfObject\$ref_to_object()
- IdfObject\$ref_by_object()
- IdfObject\$ref_to_node()
- IdfObject\$has_ref_to()
- IdfObject\$has_ref_by()
- IdfObject\$has_ref_node()
- IdfObject\$has_ref()
- IdfObject\$to_table()
- IdfObject\$to_string()
- IdfObject\$print()
- IdfObject\$clone()

Method new(): Create an IdfObject object

Usage:

```
IdfObject$new(object, class = NULL, parent)
```

Arguments:

`object` An integer specifying an object ID.

`class` An integer specifying a class index.

`parent` An [Idf](#) object specifying the parent object.

Details: It is not recommended to directly use `$new()` method to create an IdfObject object, instead considering to use `idf_object`, `Idf$object()` and other equivalent to create IdfObject objects. They provide more user-friendly interfaces. `$new()` is a lower level API which is mainly used inside methods in other classes.

Returns: An IdfObject object.

Examples:

```
\dontrun{
# example model shipped with eplusr from EnergyPlus v8.8
path_idf <- system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr") # v8.8
idf <- read_idf(path_idf, use_idd(8.8, "auto"))

roof <- IdfObject$new(26, parent = idf)

# get the IdfObject of material named "C5 - 4 IN HW CONCRETE"
mat <- idf$Material[["C5 - 4 IN HW CONCRETE"]]
}
```

Method `version()`: Get the version of parent Idf

Usage:

```
IdfObject$version()
```

Details: `$version()` returns the version of parent Idf in a `base::numeric_version()` format. This makes it easy to direction compare versions of different IdfObjects, e.g. `idfobj1$version() > 8.6` or `idfobj1$version() > idfobj2$version()`.

Returns: A `base::numeric_version()` object.

Examples:

```
\dontrun{
# get version
roof$version()
}
```

Method `parent()`: Get parent Idf

Usage:

```
IdfObject$parent()
```

Details: `$parent()` returns parent Idf object.

Returns: A Idf object.

Examples:

```
\dontrun{
roof$parent()
}
```

Method `id()`: Get the unique ID for current object

Usage:

```
IdfObject$id()
```

Details: In Idf, each object is assigned with an integer as an universally unique identifier (UUID) in the context of current Idf. UUID is not reused even if the object associated is deleted. `$id()` returns an integer of current object unique ID.

Returns: A single integer.

Examples:

```
\dontrun{
roof$id()
}
```

Method `name()`: Get the name for current object.

Usage:

```
IdfObject$name()
```

Details: In Idf, each object is assigned with a single string as the name for it, if the class it belongs to has name attribute, e.g. class RunPeriod, Material and etc. That name should be unique among all objects in that class. EnergyPlus will fail with an error if duplications are found among object names in a class.

\$name() returns a single string of current object name. If specified class does not have name attribute, NA is returned.

Returns: A single string.

Examples:

```
\dontrun{
roof$name()
```

```
# NA will be returned if the class does not have name attribute. For example,
# "Version" class
idf$Version$name()
}
```

Method group_name(): Get name of group for current object.

Usage:

```
IdfObject$group_name()
```

Details: \$group_name() returns a single string of group name current IdfObject belongs to.

Returns: A single string.

Examples:

```
\dontrun{
roof$group_name()
}
```

Method class_name(): Get name of class for current object.

Usage:

```
IdfObject$class_name()
```

Details: \$class_name() returns a single string of class name current IdfObject belongs to.

Returns: A single string.

Examples:

```
\dontrun{
roof$class_name()
}
```

Method definition(): Get the [IddObject](#) object for current class.

Usage:

```
IdfObject$definition()
```

Details: \$definition() returns an [IddObject](#) of current class. [IddObject](#) contains all data used for parsing and creating current IdfObject. For details, please see [IddObject](#) class.

Returns: An [IddObject](#) object.

Examples:

```
\dontrun{
roof$definition()
}
```

Method `comment()`: Get and modify object comments

Usage:

```
IdfObject$comment(comment, append = TRUE, width = 0L)
```

Arguments:

`comment` A character vector.

- If missing, current comments are returned. If there is no comment in current `IdfObject`, NULL is returned.
- If NULL, all comments in current `IdfObject` is deleted.
- If a character vector, it is inserted as comments depending on the `append` value.

`append` Only applicable when `comment` is a character vector. Default: FALSE.

- If NULL, existing comments is deleted before adding comment.
- If TRUE, comment will be appended to existing comments.
- If FALSE, comment is prepended to existing currents.

`width` A positive integer giving the target width for wrapping inserted comment.

Details: `$comment()` returns current `IdfObject` comments if `comment` is not given, or modifies current `IdfObject` comments if `comment` is given. If no comments found, NULL is returned.

Returns: If calling without any argument, a character vector or NULL (if no comments) is return. Otherwise, the modified object itself.

Examples:

```
\dontrun{
# get object comments
roof$comment()

# add new object comments
roof$comment(c("This is a material named `WD01`", "This object has an ID of 47"))
roof$comment()

# append new comments
roof$comment("This is an appended comment")
roof$comment()

# prepend new comments
roof$comment("This is a prepended comment", append = FALSE)
roof$comment()

# wrap long comments
roof$comment("This is a very long comment that is needed to be wrapped.", width = 30)
```

```

roof$comment()

# delete old comments and add new one
roof$comment("This is the only comment", append = NULL)
roof$comment()

# delete all comments
roof$comment(NULL)
roof$comment()
}

```

Method value(): Get object field values.

Usage:

```
IdfObject$value(which = NULL, all = FALSE, simplify = FALSE, unit = FALSE)
```

Arguments:

which An integer vector of field indexes or a character vector of field names.

all If TRUE, values of all possible fields in current class the IdfObject belongs to are returned.

Default: FALSE

simplify If TRUE, values of fields are converted into characters and the converted character vector is returned.

unit If TRUE, values of numeric fields are assigned with units using `units::set_units()` if applicable. Default: FALSE.

Details: `$value()` takes an integer vector of valid field indexes or a character vector of valid field names, and returns a named list containing values of specified fields when `simplify` is FALSE and a character vector when `simplify` is TRUE.

`eplusr` also provides custom S3 method of `$` and `[[` which make it more convenient to get a single value of current IdfObject. Basically, `idfobj$FieldName` and `idfobj[[Field]]` is equivalent to `idfobj$value(FieldName)[[1]]` and `idfobj$value(Field)[[1]]`.

Returns: A named list.

Examples:

```

\dontrun{
# get all existing field values
str(mat$value())

# get values of field 1, 3, 5
str(mat$value(c(1, 3, 5)))

# get character format values instead of a named list
mat$value(c(1, 3, 5), simplify = TRUE)

# get values of all field even those that are not set
str(roof$value())
str(roof$value(all = TRUE))

# get field values using shortcuts

```

```

mat$Roughness
mat[["Specific_Heat"]]
mat[c(1,2)]
mat[c("Name", "Density")]
}

```

Method set(): Modify object field values.

Usage:

```
IdfObject$set(..., .default = TRUE, .empty = FALSE)
```

Arguments:

... New field value definitions in `field = value` format or a single list in format:

```
list(field1 = value1, field2 = value2)
```

`.default` If TRUE, default values are used for those blank fields if possible. Default: TRUE.

`.empty` If TRUE, trailing empty fields are kept. Default: FALSE.

Details: `$set()` takes new field value definitions in `field = value` format or in a single list format, sets new values for fields specified, and returns the modified `IdfObject`. Unlike `$set()` method in `Idf` class, the special element `.comment` is **not allowed**. To modify object comments, please use `$comment()`.

Examples:

```

\dontrun{
# set field values
mat$set(name = "new_name", Thickness = 0.02)
mat[c("Name", "Thickness")]

# When `default` argument is set to TRUE and input field values are empty, i.e.
# NULL, the field values will be reset to defaults.
mat[c("Thermal Absorptance", "Solar Absorptance")]

mat$set(visible_absorptance = NULL, Solar_Absorptance = NULL, .default = TRUE)
mat[c("Visible Absorptance", "Solar Absorptance")]

# set field values using shortcuts
mat$Name <- "another_name"
mat$Name
mat[["Thickness"]] <- 0.019
mat$Thickness
}

```

Method value_possible(): Get possible object field values.

Usage:

```
IdfObject$value_possible(
  which = NULL,
  type = c("auto", "default", "choice", "range", "source")
)
```

Arguments:

which An integer vector of field indexes or a character vector of field names.

type A character vector. What types of possible values should be returned. Should be one of or a combination of "auto", "default", "choice", "range" and "source". Default: All of those.

Details: \$value_possible() takes an integer vector of valid field indexes or a character vector of valid field names, and returns all possible values for specified fields. For a specific field, there are 5 types of possible values:

- *auto*: Whether the field can be filled with Autosize and Autocalculate. This field attribute can also be retrieved using:
`idfobj$definition()$is_autosizable_field()`
`idfobj$definition()$is_autocalculatable_field()`
- *default*: The default value. This value can also be retrieved using `idfobj$definition()$field_default()`.
- *choice*: The choices which the field can be set. This value can also be retrieved using `idfobj$definition()$field_choice()`.
- *range*: The range which the field value should fall in. This range can also be retrieved using `idfobj$definition()$field_range()`.
- *source*: All values from other objects that current field can refer to.

Returns: \$value_possible() returns an IdfValuePossible object which is a [data.table](#) with at most 15 columns:

- *class_id*: index of class that current IdfObject belongs to
- *class_name*: name of class that current IdfObject belongs to
- *object_id*: ID of current IdfObject
- *object_name*: name of current IdfObject
- *field_id*: indexes (at Idd level) of object fields specified
- *field_index*: indexes of object fields specified
- *field_name*: names (without units) of object fields specified
- *value_id*: value indexes (at Idf level) of object fields specified
- *value_chr*: values (converted to characters) of object fields specified
- *value_num*: values (converted to numbers in SI units) of object fields specified.
- *auto*: Exists only when "auto" is one of type. Character type. Possible values are: "Autosize", "Autocalculate" and NA (if current field is neither autosizable nor autocalculatable).
- *default*: Exists only when "default" is one of type. List type. The default value of current field. The value is converted into number if corresponding field type yells so. Note that if current field is a numeric field but the default value is "Autosize" or "Autocalculate", it is left as it is, leaving the returned type being a string instead of a number.
- *range*: Exists only when "range" is one of type. List type. The range that field value should fall in. Every range has four components: minimum (lower limit), lower_incbounds (TRUE if the lower limit should be included), maximum (upper limit), and upper_incbounds (TRUE if the upper limit should be included). For fields of character type, empty lists are returned. For fields of numeric types with no specified ranges, minimum is set to -Inf, lower_incbounds is set to FALSE, upper is set to Inf, and upper_incbounds is set to FALSE. The field range is printed in number interval denotation.

- `source`: Exists only when "source" is one of type. List type. Each element is a character vector which includes all values from other objects that current field can use as sources and refers to.

Examples:

```
\dontrun{
mat$value_possible()
}
```

Method `validate()`: Check possible object field value errors

Usage:

```
IdfObject$validate(level = eplusr_option("validate_level"))
```

Arguments:

`level` One of "none", "draft", "final" or a list of 10 elements with same format as `custom_validate()` output.

Details: `$validate()` checks if there are errors in current `IdfObject` object under specified validation level and returns an `IdfValidity` object.

`$validate()` is useful to help avoid some common errors before running the model. By default, validation is performed when calling all methods that modify objects, e.g. `$set()` and etc.

In total, there are 10 different validate checking components:

- `required_object`: Check if required objects are missing in current `Idf`.
- `unique_object`: Check if there are multiple objects in one unique-object class. An unique-object class means that there should be at most only one object existing in that class.
- `unique_name`: Check if all objects in each class have unique names.
- `extensible`: Check if all fields in an extensible group have values. An extensible group is a set of fields that should be treated as a whole, such like the X, Y and Z vertices of a building surfaces. An extensible group should be added or deleted together. `extensible` component checks if there are some, but not all, fields in an extensible group are empty.
- `required_field`: Check if all required fields have values.
- `auto_field`: Check if all fields filled with value "Autosize" and "Autocalculate" are actual autosizable and autocalculatable fields or not.
- `type`: Check if all fields have value types complied with their definitions, i.e. character, numeric and integer fields should be filled with corresponding type of values.
- `choice`: Check if all choice fields are filled with valid choice values.
- `range`: Check if all numeric fields have values within prescribed ranges.
- `reference`: Check if all fields whose values refer to other fields are valid.

The `level` argument controls what checkings should be performed. `level` here is just a list of 10 element which specify the toggle status of each component. You can use helper `custom_validate()` to get that list and pass it directly to `level`.

There are 3 predefined validate level that indicates different combinations of checking components, i.e. `none`, `draft` and `final`. Basically, `none` level just does not perform any checkings; `draft` includes 5 components, i.e. `auto_field`, `type`, `unique_name`, `choice` and `range`; and `final` level includes all 10 components. You can always get what components each level contains using `level_checks()`. By default, the result from `eplusr_option("validate_level")` is passed to `level`. If not set, `final` level is used.

Underneath, an IdfValidity object which \$validate() returns is a list of 13 element as shown below. Each element or several elements represents the results from a single validation checking component.

- missing_object: Result of required_object checking.
- duplicate_object: Result of unique_object checking.
- conflict_name: Result of unique_name checking.
- incomplete_extensible: Result of extensible checking.
- missing_value: Result of required_field checking.
- invalid_autosize: Result of auto_field checking for invalid Autosize field values.
- invalid_autocalculate: Result of auto_field checking for invalid Autocalculate field values.
- invalid_character: Result of type checking for invalid character field values.
- invalid_numeric: Result of type checking for invalid numeric field values.
- invalid_integer: Result of type checking for invalid integer field values.
- invalid_choice: Result of choice checking.
- invalid_range: Result of range checking.
- invalid_reference: Result of reference checking.

Except missing_object, which is a character vector of class names that are missing, all other elements are [data.table](#) with 9 columns containing data of invalid field values:

- object_id: IDs of objects that contain invalid values
- object_name: names of objects that contain invalid values
- class_id: indexes of classes that invalid objects belong to
- class_name: names of classes that invalid objects belong to
- field_id: indexes (at Idd level) of object fields that are invalid
- field_index: indexes of object fields in corresponding that are invalid
- field_name: names (without units) of object fields that are invalid
- units: SI units of object fields that are invalid
- ip_units: IP units of object fields that are invalid
- type_enum: An integer vector indicates types of invalid fields
- value_id: indexes (at Idf level) of object field values that are invalid
- value_chr: values (converted to characters) of object fields that are invalid
- value_num: values (converted to numbers in SI units) of object fields that are invalid

Knowing the internal structure of IdfValidity, it is easy to extract invalid [IdfObjects](#) you interested in. For example, you can get all IDs of objects that contain invalid value references using `model$validate()$invalid_reference$object_id`. Then using `$set()` method to correct them.

Different validate result examples are shown below:

- No error is found:
 - v No error found.
 - Above result shows that there is no error found after conducting all validate checks in specified validate level.
- Errors are found:

```

x [2] Errors found during validation.
=====

-- [2] Invalid Autocalculate Field -----
Fields below cannot be `autocalculate`:

Class: <AirTerminal:SingleDuct:VAV:Reheat>
\~ Object [ID:176] <SPACE5-1 VAV Reheat>
+- 17: AUTOCALCULATE, !- Maximum Flow per Zone Floor Area During Reheat {m3/s-m2}
  \~ 18: AUTOCALCULATE; !- Maximum Flow Fraction During Reheat
Above result shows that after all validate components performed under current validate
level, 2 invalid field values are found. All of them are in a object named SPACE5-1 VAV Re-
heat with ID 176. They are invalid because those two fields do not have an autocalculatable
attribute but are given AUTOCALCULATE value. Knowing this info, one simple way to fix the
error is to correct those two fields by doing:
idf$set(..176 =
  list(`Maximum Flow per Zone Floor Area During Reheat` = "autosize",
       `Maximum Flow Fraction During Reheat` = "autosize"
  )
)

```

Returns: An IdfValidity object.

Examples:

```

\dontrun{
mat$validate()

# check at predefined validate level
mat$validate("none")
mat$validate("draft")
mat$validate("final")

# custom validate checking components
mat$validate(custom_validate(auto_field = TRUE, choice = TRUE))
}

```

Method `is_valid()`: Check if there is any error in current object

Usage:

```
IdfObject$is_valid(level = eplusr_option("validate_level"))
```

Arguments:

`level` One of "none", "draft", "final" or a list of 10 elements with same format as `custom_validate()` output.

Details: `$is_valid()` returns TRUE if there is no error in current IdfObject object under specified validation level and FALSE otherwise.

`$is_valid()` checks if there are errors in current IdfObject object under specified validation level and returns TRUE or FALSE accordingly. For detailed description on validate checking, see `$validate()` documentation above.

Returns: A single logical value of TRUE or FALSE.

Examples:

```
\dontrun{
mat$sis_valid()

mat$definition()$field_range("Density")
eplusr_option(validate_level = "none") # have to set validate to "none" to do so
mat$Density <- -1
eplusr_option(validate_level = "final") # change back to "final" validate level
mat$sis_valid()

# check at predefined validate level
mat$sis_valid("none")
mat$sis_valid("draft")
mat$sis_valid("final")

# custom validate checking components
mat$sis_valid(custom_validate(auto_field = TRUE, choice = TRUE))
}
```

Method `value_relation()`: Get value relations

Usage:

```
IdfObject$value_relation(
  which = NULL,
  direction = c("all", "ref_to", "ref_by", "node"),
  recursive = FALSE,
  depth = 1L
)
```

Arguments:

`which` An integer vector of field indexes or a character vector of field names.

`direction` The relation direction to extract. Should be either "all", "ref_to" or "ref_by".

`recursive` If TRUE, the relation is searched recursively. A simple example of recursive reference: one material named `mat` is referred by a construction named `const`, and `const` is also referred by a surface named `surf`.

`depth` Only applicable when `recursive` is TRUE. This is a depth to when searching value relations recursively. If NULL, all recursive relations are returned. Default: 1.

`class` A character vector of class names.

Details: Many fields in `Idd` can be referred by others. For example, the Outside Layer and other fields in Construction class refer to the Name field in Material class and other material related classes. Here it means that the Outside Layer field **refers to** the Name field and the Name field is **referred by** the Outside Layer. In EnergyPlus, there is also a special type of field called Node, which together with Branch and BranchList define the topography of the HVAC connections. A outlet node of a component can be referred by another component as its inlet node, but can also exist independently, such as zone air node.

`$value_relation()` provides a simple interface to get this kind of relation. It takes field indexes or field names, together a relation direction, and returns an `IdfRelation` object which contains

data presenting such relation described above. For instance, if `idfobj$value_relation("Name", "ref_by")` gives results below:

```
-- Referred by Others -----
\~ 1: "WALL-1";      !~ Name
   ^~~~~~
   \~ Class: <BuildingSurface:Detailed>
     \~ Object [ID:3] <WALL-1PF>
       \~ 3: "WALL-1";      !~ Construction Name
```

This means that the value "WALL-1" of field Name is referred by field Construction Name in a surface named WALL-1PF. All those objects can be further easily extracted using `$ref_by_object()` method.

Note that `$value_relation()` shows all fields specified, even some of them may do not have relation.

Returns: An `IdfRelation` object, which is a list of 3 `data.table::data.table()`s named `ref_to`, `ref_by` and `node`. Each `data.table::data.table()` contains 24 columns.

Examples:

```
\dontrun{
# check each layer's reference of a construction named FLOOR
roof$value_relation("zone name", "ref_to")

# check where is this construction being used
roof$value_relation("name", direction = "ref_by")
}
```

Method `ref_to_object()`: Extract multiple `IdfObject` objects referred by specified field values

Usage:

```
IdfObject$ref_to_object(
  which = NULL,
  class = NULL,
  recursive = FALSE,
  depth = 1L
)
```

Arguments:

`which` An integer vector of field indexes or a character vector of field names.

`class` A character vector of class names.

`recursive` If TRUE, the relation is searched recursively. A simple example of recursive reference: one material named `mat` is referred by a construction named `const`, and `const` is also referred by a surface named `surf`.

`depth` Only applicable when `recursive` is TRUE. This is a depth to when searching value relations recursively. If NULL, all recursive relations are returned. Default: 1.

Details: For details on field value relations, see `$value_relation()`.

`$ref_to_object()` takes an integer vector of field indexes or a character vector of field names, and returns a list of `IdfObjects` that specified fields refer to.

Returns: A named list of IdfObject objects.

Examples:

```
\dontrun{
# get other objects that this object refereces
mat$ref_to_object() # not referencing other objects
}
```

Method `ref_by_object()`: Extract multiple IdfObject objects referring to specified field values

Usage:

```
IdfObject$ref_by_object(
  which = NULL,
  class = NULL,
  recursive = FALSE,
  depth = 1L
)
```

Arguments:

`which` An integer vector of field indexes or a character vector of field names.

`class` A character vector of class names.

`recursive` If TRUE, the relation is searched recursively. A simple example of recursive reference: one material named `mat` is referred by a construction named `const`, and `const` is also referred by a surface named `surf`.

`depth` Only applicable when `recursive` is TRUE. This is a depth to when searching value relations recursively. If NULL, all recursive relations are returned. Default: 1.

Details: For details on field value relations, see [\\$value_relation\(\)](#).

`$ref_by_object()` takes an integer vector of field indexes or a character vector of field names, and returns a list of IdfObjects that refer to specified fields.

Returns: A named list of IdfObject objects.

Examples:

```
\dontrun{
# get other objects that reference this object
mat$ref_by_object() # referenced by construction "FLOOR"
}
```

Method `ref_to_node()`: Extract multiple IdfObject objects referring to same nodes

Usage:

```
IdfObject$ref_to_node(
  which = NULL,
  class = NULL,
  recursive = FALSE,
  depth = 1L
)
```

Arguments:

which An integer vector of field indexes or a character vector of field names.

class A character vector of class names.

recursive If TRUE, the relation is searched recursively. A simple example of recursive reference: one material named mat is referred by a construction named const, and const is also referred by a surface named surf.

depth Only applicable when recursive is TRUE. This is a depth to when searching value relations recursively. If NULL, all recursive relations are returned. Default: 1.

Details: For details on field value relations, see `$value_relation()`.

`$ref_to_node()` takes an integer vector of field indexes or a character vector of field names, and returns a list of IdfObjects whose nodes are referred by specified fields.

Returns: A named list of IdfObject objects.

Examples:

```
\dontrun{
if (is_avail_eplus(8.8)) {
  path <- file.path(eplus_config(8.8)$dir, "ExampleFiles/5Zone_Transformer.idf")
  idf_5z <- read_idf(path)
  idf_5z$NodeList$OutsideAirInletNodes$ref_to_node()
}
}
```

Method `has_ref_to()`: Check if object field values refer to others

Usage:

```
IdfObject$has_ref_to(which = NULL, class = NULL)
```

Arguments:

which An integer vector of field indexes or a character vector of field names.

class A character vector of class names.

Details: For details on field value relations, see `$value_relation()`.

`$has_ref_to()` takes an integer vector of field indexes or a character vector of field names, and returns a logical vector showing whether specified fields refer to other object values or not.

Returns: A logical vector with the same length as specified field.

Examples:

```
\dontrun{
mat$has_ref_to()
}
```

Method `has_ref_by()`: Check if object field values are referred by others

Usage:

```
IdfObject$has_ref_by(which = NULL, class = NULL)
```

Arguments:

which An integer vector of field indexes or a character vector of field names.

class A character vector of class names.

Details: For details on field value relations, see [\\$value_relation\(\)](#).

`$has_ref_by()` takes an integer vector of field indexes or a character vector of field names, and returns a logical vector showing whether there are other object values ref to specified fields.

Returns: A logical vector with the same length as specified field.

Examples:

```
\dontrun{
mat$has_ref_by()
}
```

Method `has_ref_node()`: Check if object field values refer to other nodes

Usage:

```
IdfObject$has_ref_node(which = NULL, class = NULL)
```

Arguments:

`which` An integer vector of field indexes or a character vector of field names.

`class` A character vector of class names.

Details: For details on field value relations, see [\\$value_relation\(\)](#).

`$has_ref_node()` takes an integer vector of field indexes or a character vector of field names, and returns a logical vector showing whether specified fields refer to other objects' nodes.

Returns: A logical vector with the same length as specified field.

Examples:

```
\dontrun{
mat$has_ref_node()
}
```

Method `has_ref()`: Check if object field values refer to or are referred by others

Usage:

```
IdfObject$has_ref(which = NULL)
```

Arguments:

`which` An integer vector of field indexes or a character vector of field names.

Details: For details on field value relations, see [\\$value_relation\(\)](#).

`$has_ref()` takes an integer vector of field indexes or a character vector of field names, and returns a logical vector showing whether there are other object values ref to specified field values or specified field values refer to other object values or specified field values refer to other objects' nodes.

Returns: A logical vector with the same length as specified field.

Examples:

```
\dontrun{
# check if having any referenced objects or is referenced by other objects
mat$has_ref()
}
```

Method `to_table()`: Format IdfObject as a data.frame

Usage:

```
IdfObject$to_table(
  string_value = TRUE,
  unit = TRUE,
  wide = FALSE,
  all = FALSE,
  group_ext = c("none", "group", "index")
)
```

Arguments:

`string_value` If TRUE, all field values are returned as character. If FALSE, value column in returned `data.table` is a list column with each value stored as corresponding type. Note that if the value of numeric field is set to "Autosize" or "Autocalculate", it is left as it is, leaving the returned type being a string instead of a number. Default: TRUE.

`unit` Only applicable when `string_value` is FALSE. If TRUE, values of numeric fields are assigned with units using `units::set_units()` if applicable. Default: FALSE.

`wide` Only applicable if target objects belong to a same class. If TRUE, a wide table will be returned, i.e. first three columns are always `id`, `name` and `class`, and then every field in a separate column. Note that this requires all objects specified must from the same class. Default: FALSE.

`all` If TRUE, all available fields defined in IDD for the class that objects belong to will be returned. Default: FALSE.

`group_ext` Should be one of "none", "group" or "index". If not "none", value column in returned `data.table::data.table()` will be converted into a list. If "group", values from extensible fields will be grouped by the extensible group they belong to. For example, coordinate values of each vertex in class `BuildingSurface:Detailed` will be put into a list. If "index", values from extensible fields will be grouped by the extensible field indice they belong to. For example, coordinate values of all x coordinates will be put into a list. If "none", nothing special will be done. Default: "none".

Details: `Sto_table()` returns a `data.table` that contains core data of current IdfObject. It has 6 columns:

- `id`: Integer type. Object IDs.
- `name`: Character type. Object names.
- `class`: Character type. Current class name.
- `index`: Integer type. Field indexes.
- `field`: Character type. Field names.
- `value`: Character type if `string_value` is TRUE or list type if `string_value` is FALSE or `group_ext` is not "none". Field values.

Note that when `group_ext` is not "none", `index` and `field` values will not match the original field indices and names. In this case, `index` will only indicate the indices of sequences. For `field` column, specifically:

- When `group_ext` is "group", each field name in a extensible group will be abbreviated using `abbreviate()` with `minlength` being 10L and all abbreviated names will be separated by | and combined together. For example, field names in the extensible group (Vertex 1 X-coordinate, Vertex 1 Y-coordinate, Vertex 1 Z-coordinate) in class `BuildiBuildingSurface:Detailed` will be merged into one name `Vrtx1X-crd|Vrtx1Y-crd|Vrtx1Z-crd`.

- When `group_ext` is "index", the extensible group indicator in field names will be removed. Take the same example as above, the resulting field names will be Vertex X-coordinate, Vertex Y-coordinate, and Vertex Z-coordinate.

Returns: A [data.table](#) with 6 columns (if `wide` is FALSE) or at least 6 columns (if `wide` is TRUE).

Examples:

```
\dontrun{
# get all object data in a data.table format without field units
str(mat$to_table(unit = FALSE))

# get all object data in a data.table format where all field values are put in a
# list column and field names without unit
str(mat$to_table(string_value = FALSE, unit = FALSE))

# get all object data in a data.table format, including trailing empty fields
str(idf$Zone$`ZONE ONE`$to_table(all = TRUE))

# get all object data in a data.table format where each field becomes a column
str(mat$to_table(wide = TRUE))

# group extensible by extensible group number
surf <- idf$BuildingSurface_Detailed[["Zn001:Roof001"]]
surf$to_table(group_ext = "group")

# group extensible by extensible group number and convert into a wide table
surf$to_table(group_ext = "group", wide = TRUE)

# group extensible by extensible field index
surf$to_table(group_ext = "index")

# group extensible by extensible field index and convert into a wide table
surf$to_table(group_ext = "index", wide = TRUE)

# when grouping extensible, 'string_value' and 'unit' still take effect
surf$to_table(group_ext = "index", wide = TRUE, string_value = FALSE, unit = TRUE)
}
```

Method `to_string()`: Format current object as a character vector

Usage:

```
IdfObject$to_string(comment = TRUE, leading = 4L, sep_at = 29L, all = FALSE)
```

Arguments:

`comment` If FALSE, all comments will not be included. Default: TRUE.

`leading` Leading spaces added to each field. Default: 4L.

`sep_at` The character width to separate value string and field string. Default: 29L which is the same as IDF Editor.

`all` If TRUE, all available fields defined in IDD for the class that objects belong to will be returned. Default: FALSE.

Details: \$to_string() returns the text format of current object.

Returns: A character vector.

Examples:

```
\dontrun{
# get string format object
mat$to_string()

# get string format of object, and decrease the space between field values and
# field names
mat$to_string(sep_at = 15)

# get string format of object, and decrease the leading space of field values
mat$to_string(leading = 0)
}
```

Method print(): Print IdfObject object

Usage:

```
IdfObject$print(comment = TRUE, auto_sep = TRUE, brief = FALSE)
```

Arguments:

comment If FALSE, all comments are not included.

auto_sep If TRUE, values and field names are separated at the largest character length of values.
Default: FALSE.

brief If TRUE, only OBJECT part is printed. Default: FALSE.

Details: \$print() prints the IdfObject. Basically, the print output can be divided into 3 parts:

- OBJECT: Class name, object id and name (if applicable).
- COMMENTS: Object comments if exist.
- VALUES: fields and values of current IdfObject. Required fields are marked with start *.
String values are quoted. Numeric values are printed as they are. Blank string values are printed as <"Blank"> and blank number values are printed as <Blank>.

Returns: The IdfObject itself, invisibly.

Examples:

```
\dontrun{
# print the object without comment
mat$print(comment = FALSE)

# print the object, and auto separate field values and field names at the
# largest character length of field values
mat$print(auto_sep = TRUE)
}
```

Method clone(): The objects of this class are cloneable with this method.

Usage:

```
IdfObject$clone(deep = FALSE)
```

Arguments:

deep Whether to make a deep clone.

Note

- Only one single list is allowed, e.g. `idfobj$set(lst1)` where `lst1 <- list(field1 = value1)` is allowed, but `idfobj$set(lst1, lst2)` is not.
- You can delete a field by assigning `NULL` to it, e.g. `iddobj$set(fld = NULL)` means to delete the value of field `fld`. If `.default` is `FALSE`, also `fld` is not a required field and the index of `fld` is larger than the number minimum fields required for that class, it will be deleted. Otherwise it will be left as blank. If `.default` is `TRUE`, that field will be filled with default value if applicable and left as blank if not.
- By default, trailing empty fields that are not required will be removed and only minimum required fields are kept. You can keep the trailing empty fields by setting `.empty` to `TRUE`.
- New fields that currently do not exist in that object can also be set. They will be automatically added on the fly.
- Field name matching is **case-insensitive**. For convenience, underscore-style field names are also allowed, e.g. `eNd_MoNtH` is equivalent to `End Month`.
- If not all field names are given, positions of those values without field names are determined after those values with names. E.g. in `model$set(Construction = list("out_layer", name = "name"))`, `"out_layer"` will be treated as the value of field `Outside Layer` in `Construction`, as value of field `Name` has been given as `"name"`.

`eplusr` also provides custom `S3` method of `$<-` and `[[<-` which makes it more convenient to set a single field value of an `IdfObject`. Basically, `idfobj$FieldName <- value` and `idfobj[[Field]] <- value` is equivalent to `idfobj$set(FieldName = value)` and `idfobjset(Field = value)`.

idf_object	<i>Create an IdfObject object.</i>
------------	------------------------------------

Description

`idf_object()` takes a parent `Idf` object, an object name or class name, and returns a corresponding [IdfObject](#).

Usage

```
idf_object(parent, object = NULL, class = NULL)
```

Arguments

<code>parent</code>	An Idf object.
<code>object</code>	A valid object ID (an integer) or name (a string). If <code>NULL</code> and <code>class</code> is not <code>NULL</code> , an empty IdfObject is created with all fields fill with default values if possible. Default: <code>NULL</code> .
<code>class</code>	A valid class name (a string). If <code>object</code> is not <code>NULL</code> , <code>class</code> is used to further specify what class is the target object belongs to. If <code>object</code> is <code>NULL</code> , an empty IdfObject of <code>class</code> is created.

Details

If `object` is not given, an empty [IdfObject](#) of specified class is created, with all field values filled with defaults, if possible. Note that validation is performed when creating, which means that an error may occur if current [validate level](#) does not allow empty required fields.

The empty [IdfObject](#) is directly added into the parent [Idf](#) object. It is recommended to use `$validate()` method in [IdfObject](#) to see what kinds of further modifications are needed for those empty fields and use `$set()` method to set field values.

Value

An [IdfObject](#) object.

Examples

```
## Not run:
model <- read_idf(system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr"))

# get an IdfObject using object ID
idf_object(model, 14)

# get an IdfObject using object name (case-insensitive)
idf_object(model, "zone one")

# `class` argument is useful when there are objects with same name in
# different class
idf_object(model, "zone one", "Zone")

# create a new zone
eplusr_option(validate_level = "draft")
zone <- idf_object(model, class = "Zone")
zone
eplusr_option(validate_level = "final")
zone$validate()

## End(Not run)
```

install_eplus

Download and Install EnergyPlus

Description

Download specified version of EnergyPlus for your platform from GitHub and install it.

Usage

```
install_eplus(ver = "latest", local = FALSE, dir = NULL, force = FALSE, ...)
```

```
download_eplus(ver = "latest", dir)
```

Arguments

ver	The EnergyPlus version number, e.g., 8.7. The special value "latest", which is the default, means the latest version.
local	Whether to install EnergyPlus only for current user. For Windows and Linux, if FALSE, administrative privileges are required to install EnergyPlus to the default system-level location. See details. local should be also set to FALSE if you do not have the write access to the directory specified via dir. Default: FALSE. For macOS, administrative privileges are always required no matter you want EnergyPlus to be install at /Applications or ~/Applications.
dir	<ul style="list-style-type: none"> For download_eplus(), where to save EnergyPlus installer file. Default: ".".

- For `install_eplus()`, the installer will always be saved into `tempdir()`. But you can use `dir` to specify the **parent** directory of EnergyPlus installation, i.e. the **parent** directory of `EnergyPlusVX-Y-0` on Windows and `EnergyPlus-X-Y-0` on Linux. macOS is not supported. If `NULL`, the default installation path will be used. See details for more information. Please note that `dir` does not work on macOS and EnergyPlus will always be installed into the default location. Default: `NULL`.
- `force` Whether to install EnergyPlus even if it has already been installed.
- `...` Other arguments to be passed to the installer. Current only one additional argument exists and is only for Linux: `* dir_bin`: A path where symbolic links will be created to the software executables. The default is `/usr/local/bin` if `local` is `FALSE` and `~/local/bin` if `local` is `TRUE`.

Details

`download_eplus()` downloads specified version of EnergyPlus from [EnergyPlus GitHub Repository](#).

`install_eplus()` will try to install EnergyPlus into the default location, e.g. `C:\EnergyPlusVX-Y-0` on Windows, `/usr/local/EnergyPlus-X-Y-0` on Linux, and `/Applications/EnergyPlus-X-Y-0` on macOS.

Note that installing to the default location requires administrative privileges and you have to run R with administrator (or with `sudo` if you are on Linux) to make it work if you are not in interactive mode.

If you can't run R with administrator, it is possible to install EnergyPlus to your home corresponding directory by setting `local` to `TRUE`.

The user level EnergyPlus installation path is:

- Windows:
 - `dir(Sys.getenv("LOCALAPPDATA"), "EnergyPlusVX-Y-0")` OR
 - `C:\Users\<User>\AppData\Local\EnergyPlusVX-Y-0` if environment variable "LOCALAPPDATA" is not set
- macOS: `/Users/<User>/Applications/EnergyPlus-X-Y-0`
- Linux: `"~/local/EnergyPlus-X-Y-0"`

On Windows and Linux, you can also specify your custom directory using the `dir` argument. Remember to change `local` to `FALSE` in order to ask for administrator privileges if you do not have the write access to that directory.

Please note that on macOS, when `local` is set to `FALSE`, no symbolic links will be created, since this process requires administrative privileges.

Value

An invisible integer `0` if succeed. Moreover, some attributes will also be returned:

- For `install_eplus()`:
 - `path`: the EnergyPlus installation path

- installer: the path of downloaded EnergyPlus installer file
- For download_eplus():
 - file: the path of downloaded EnergyPlus installer file

Author(s)

Hongyuan Jia

Examples

```
## Not run:
# download the latest version of EnergyPlus
download_eplus("latest", dir = tempdir())
# install the latest version of EnergyPlus system-wide which is the default
# and requires administrative privileges
install_eplus("latest")

# for a specific version of EnergyPlus
download_eplus(8.8, dir = tempdir())
install_eplus(8.8)

# force to reinstall
install_eplus(8.8, force = TRUE)

# install EnergyPlus in your home directory
install_eplus(8.8, local = TRUE, force = TRUE)

# custom EnergyPlus install home directory
install_eplus(8.8, dir = "~/MyPrograms", local = TRUE, force = TRUE)

## End(Not run)
```

is_eplus_ver

Check for Idd, Idf and Epw objects

Description

These functions test if input is a valid object of Idd, Idf, Epw and other main classes.

Usage

```
is_eplus_ver(ver, strict = FALSE)

is_idd_ver(ver, strict = FALSE)

is_eplus_path(path)

is_idd(x)
```

```

is_idf(x)

is_iddobject(x)

is_idfobject(x)

is_epw(x)

```

Arguments

ver	A character or numeric vector with suitable numeric version strings.
strict	If FALSE, ver can be a special string "latest" which represents the latest version.
path	A path to test.
x	An object to test.

Details

is_eplus_ver() returns TRUE if input is a valid EnergyPlus version.

is_idd_ver() returns TRUE if input is a valid EnergyPlus IDD version.

is_eplus_path() returns TRUE if input path is a valid EnergyPlus path, i.e. a path where there is an energyplus executable and an Energy+.idd file.

is_idd() returns TRUE if input is an Idd object.

is_idf() returns TRUE if input is an Idf object.

is_iddobject() returns TRUE if input is an IddObject object.

is_idfobject() returns TRUE if input is an IdfObject object.

is_epw() returns TRUE if input is an Epw object.

Value

A logical vector.

Examples

```

is_eplus_ver(8.8)
is_eplus_ver(8.0)
is_eplus_ver("latest", strict = FALSE)

is_idd_ver("9.0.1")
is_idd_ver("8.0.1")

is_eplus_path("C:/EnergyPlusV9-0-0")
is_eplus_path("/usr/local/EnergyPlus-9-0-1")

is_idd(use_idd(8.8, download = "auto"))

idf <- read_idf(system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr"),

```

```
    idd = use_idd(8.8, download = "auto")
is_idf(idf)

is_iddobject(idd_object(8.8, "Version"))

is_idfobject(idf_object(idf, 1))

## Not run:
is_epw(read_epw(download_weather("los angeles.*tmy3", type = "epw", ask = FALSE, max_match = 1)))

## End(Not run)
```

level_checks

Show components of validation strictness level

Description

level_checks() takes input of a built in validation level or a custom validation level and returns a list with all validation components that level contains.

Usage

```
level_checks(level = eplusr_option("validate_level"))
```

Arguments

level Should be one of "none", "draft", "final" or an output of [custom_validate\(\)](#).

Value

A named list with 10 elements, e.g. required_object, unique_object, unique_name, extensible, required_field, auto_field, type, choice, range and reference. For the meaning of each validation component, see [custom_validate\(\)](#).

Examples

```
level_checks("draft")
level_checks("final")
level_checks(custom_validate(auto_field = TRUE))
level_checks(eplusr_option("validate_level"))
```

Description

ParametricJob class provides a prototype of conducting parametric analysis of EnergyPlus simulations.

Details

Basically, it is a collection of multiple EplusJob objects. However, the model is first parsed and the [Idf](#) object is stored internally, instead of storing only the path of Idf like in [EplusJob](#) class. Also, an object in Output:SQLite with Option Type value of SimpleAndTabular will be automatically created if it does not exist, like [Idf](#) class does.

Super class

[eplusr::EplusGroupJob](#) -> ParametricJob

Methods

Public methods:

- [ParametricJob\\$new\(\)](#)
- [ParametricJob\\$version\(\)](#)
- [ParametricJob\\$seed\(\)](#)
- [ParametricJob\\$weather\(\)](#)
- [ParametricJob\\$models\(\)](#)
- [ParametricJob\\$apply_measure\(\)](#)
- [ParametricJob\\$save\(\)](#)
- [ParametricJob\\$run\(\)](#)
- [ParametricJob\\$print\(\)](#)

Method [new\(\)](#): Create a ParametricJob object

Usage:

```
ParametricJob$new(idf, epw)
```

Arguments:

idf Path to EnergyPlus IDF file or an Idf object.

epw Path to EnergyPlus EPW file or an Epw object. epw can also be NULL which will force design-day-only simulation when [\\$run\(\)](#) method is called. Note this needs at least one [Sizing:DesignDay](#) object exists in the [Idf](#).

Returns: A ParametricJob object.

Examples:

```

\dontrun{
if (is_avail_eplus(8.8)) {
  idf_name <- "1ZoneUncontrolled.idf"
  epw_name <- "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"

  idf_path <- file.path(eplus_config(8.8)$dir, "ExampleFiles", idf_name)
  epw_path <- file.path(eplus_config(8.8)$dir, "WeatherData", epw_name)

  # create from an Idf and an Epw object
  param <- ParametricJob$new(idf_path, epw_path)
}
}

```

Method `version()`: Get the version of seed IDF

Usage:

```
ParametricJob$version()
```

Details: `$version()` returns the version of input seed [Idf](#) object.

Returns: A `base::numeric_version()` object.

Examples:

```

\dontrun{
param$version()
}

```

Method `seed()`: Get the seed [Idf](#) object

Usage:

```
ParametricJob$seed()
```

Details: `$seed()` returns the parsed input seed [Idf](#) object.

Examples:

```

\dontrun{
param$seed()
}

```

Method `weather()`: Get the [Epw](#) object

Usage:

```
ParametricJob$weather()
```

Details: `$weather()` returns the input [Epw](#) object. If no [Epw](#) is provided when creating the `ParametricJob` object, `NULL` is returned.

Examples:

```

\dontrun{
param$weather()
}

```

Method `models()`: Get created parametric `Idf` objects

Usage:

```
ParametricJob$models()
```

Details: `$models()` returns a list of parametric models generated using input `Idf` object and `$apply_measure()` method. Model names are assigned in the same way as the `.names` argument in `$apply_measure()`. If no measure has been applied, `NULL` is returned. Note that it is not recommended to conduct any extra modification on those models directly, after they were created using `$apply_measure()`, as this may lead to an un-reproducible process. A warning message will be issued if any of those models has been modified when running simulations.

Examples:

```
\dontrun{
param$models()
}
```

Method `apply_measure()`: Create parametric models

Usage:

```
ParametricJob$apply_measure(measure, ..., .names = NULL)
```

Arguments:

`measure` A function that takes an `Idf` and other arguments as input and returns an `Idf` object as output.

`...` Arguments **except first** `Idf` **argument** that are passed to that measure.

`.names` A character vector of the names of parametric `Idfs`. If `NULL`, the new `Idfs` will be named in format `measure_name + number`.

Details: `$apply_measure()` allows to apply a measure to an `Idf` and creates parametric models for analysis. Basically, a measure is just a function that takes an `Idf` object and other arguments as input, and returns a modified `Idf` object as output. Use `...` to supply different arguments, **except for the first** `Idf` **argument**, to that measure. Under the hook, `base::mapply()` is used to create multiple `Idfs` according to the input values.

Returns: The modified `ParametricJob` object itself, invisibly.

Examples:

```
\dontrun{
# create a measure to change the orientation of the building
rotate_building <- function (idf, degree = 0L) {
  if (!idf$is_valid_class("Building")) {
    stop("Input model does not have a Building object")
  }

  if (degree > 360 || degree < -360 ) {
    stop("Input degree should in range [-360, 360]")
  }

  cur <- idf$Building$North_Axis

  new <- cur + degree
}
```

```

    if (new > 360) {
      new <- new %% 360
      warning("Calculated new north axis is greater than 360. ",
             "Final north axis will be ", new
            )
    } else if (new < -360) {
      new <- new %% -360
      warning("Calculated new north axis is smaller than -360. ",
             "Final north axis will be ", new
            )
    }

    idf$Building$North_Axis <- new

  idf
}

# apply measure
# this will create 12 models
param$apply_measure(rotate_building, degree = seq(30, 360, 30))

# apply measure with new names specified
param$apply_measure(rotate_building, degree = seq(30, 360, 30),
                    .names = paste0("rotate_", seq(30, 360, 30))
)
}

```

Method `save()`: Save parametric models

Usage:

```
ParametricJob$save(dir = NULL, separate = TRUE, copy_external = FALSE)
```

Arguments:

`dir` The parent output directory for models to be saved. If `NULL`, the directory of the seed model will be used. Default: `NULL`.

`separate` If `TRUE`, all models are saved in a separate folder with each model's name under specified directory. If `FALSE`, all models are saved in the specified directory. Default: `TRUE`.

`copy_external` Only applicable when `separate` is `TRUE`. If `TRUE`, the external files that every `Idf` object depends on will also be copied into the saving directory. The values of file paths in the `Idf` will be changed automatically. Currently, only `Schedule:File` class is supported. This ensures that the output directory will have all files needed for the model to run. Default: `FALSE`.

Details: `$save()` saves all parametric models in specified folder. An error will be issued if no measure has been applied.

Returns: A `data.table::data.table()` with two columns:

- `model`: The path of saved parametric model files.

- `weather`: The path of saved weather files.

Examples:

```
\dontrun{
# save all parametric models with each model in a separate folder
param$save(tempdir())

# save all parametric models with all models in the same folder
param$save(tempdir(), separate = FALSE)
}
```

Method `run()`: Run parametric simulations

Usage:

```
ParametricJob$run(
  dir = NULL,
  wait = TRUE,
  force = FALSE,
  copy_external = FALSE,
  echo = wait
)
```

Arguments:

`dir` The parent output directory for specified simulations. Outputs of each simulation are placed in a separate folder under the parent directory.

`wait` If TRUE, R will hang on and wait all EnergyPlus simulations finish. If FALSE, all EnergyPlus simulations are run in the background. Default: TRUE.

`force` Only applicable when the last simulation runs with `wait` equals to FALSE and is still running. If TRUE, current running job is forced to stop and a new one will start. Default: FALSE.

`copy_external` If TRUE, the external files that current `Idf` object depends on will also be copied into the simulation output directory. The values of file paths in the `Idf` will be changed automatically. Currently, only `Schedule:File` class is supported. This ensures that the output directory will have all files needed for the model to run. Default is FALSE.

`echo` Only applicable when `wait` is TRUE. Whether to simulation status. Default: same as `wait`.

Details: `$run()` runs all parametric simulations in parallel. The number of parallel EnergyPlus process can be controlled by `eplusr_option("num_parallel")`. If `wait` is FALSE, then the job will be run in the background. You can get updated job status by just printing the `ParametricJob` object.

Returns: The `ParametricJob` object itself, invisibly.

Examples:

```
\dontrun{
# run parametric simulations
param$run(wait = TRUE, echo = FALSE)

# run in background
param$run(wait = FALSE)
```

```
# get detailed job status by printing
print(param)
}
```

Method print(): Print ParametricJob object

Usage:

```
ParametricJob$print()
```

Details: \$print() shows the core information of this ParametricJob, including the path of IDFs and EPWs and also the simulation job status.

\$print() is quite useful to get the simulation status, especially when wait is FALSE in \$run(). The job status will be updated and printed whenever \$print() is called.

Returns: The ParametricJob object itself, invisibly.

Examples:

```
\dontrun{
param$print()

Sys.sleep(10)
param$print()
}
```

param_job

Create An EnergyPlus Parametric Simulation Job

Description

param_job() takes an IDF and EPW as input and returns a ParametricJob. For details on ParametricJob, please see [ParametricJob](#) class.

Usage

```
param_job(idf, epw)
```

Arguments

idf	A path to EnergyPlus IDF or IMF file or an Idf object.
epw	A path to EnergyPlus EPW file or an Epw object. epw can also be NULL which will force design-day-only simulation when <code>\$run()</code> method is called. Note this needs at least one Sizing:DesignDay object exists in the Idf .

Value

A ParametricJob object.

Author(s)

Hongyuan Jia

See Also

[eplus_job\(\)](#) for creating an EnergyPlus single simulation job.

Examples

```
## Not run:
if (is_avail_eplus(8.8)) {
  idf_name <- "1ZoneUncontrolled.idf"
  epw_name <- "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"

  idf_path <- file.path(eplus_config(8.8)$dir, "ExampleFiles", idf_name)
  epw_path <- file.path(eplus_config(8.8)$dir, "WeatherData", epw_name)

  # create from local files
  param_job(idf_path, epw_path)

  # create from an Idf and an Epw object
  param_job(read_idf(idf_path), read_epw(epw_path))
}

## End(Not run)
```

print.ErrFile

Print EnergyPlus Error File

Description

ErrFile is mainly used to extract and print data in an EnergyPlus Error File (.err).

Usage

```
## S3 method for class 'ErrFile'
print(x, brief = FALSE, info = TRUE, ...)
```

Arguments

x	An ErrFile created using read_err() .
brief	If TRUE, only summary data is printed. Default: FALSE.
info	If FALSE, informative messages are excluded. Only warnings and errors are printed. Default: TRUE.
...	Further arguments passed to or from other methods.

Value

An ErrFile object, invisibly.

rdd_to_load

*Format RddFile Object to Standard Input for Idf\$load() Method***Description**

rdd_to_load() and mdd_to_load() takes a RddFile and MddFile object respectively and format it into a [data.table](#) in acceptable format for \$load() method in [Idf](#) class.

Usage

```
rdd_to_load(rdd, key_value, reporting_frequency)

mdd_to_load(
  mdd,
  reporting_frequency,
  class = c("Output:Meter", "Output:Meter:MeterFileOnly", "Output:Meter:Cumulative",
            "Output:Meter:Cumulative:MeterFileOnly")
)
```

Arguments

rdd, mdd	A RddFile object created using read_rdd() and a MddFile object created using read_mdd() , respectively.
key_value	Key value name for all variables. If not specified and the key_value column in the input RddFile object will be used. If key_value column does not exist, "*" are used for all variables.
reporting_frequency	Variable value reporting frequency for all variables. If not specified and the reporting_frequency column in the input RddFile object will be used. If reporting_frequency column does not exist, "Timestep" are used for all variables. All possible values: "Detailed", "Timestep", "Hourly", "Daily", "Monthly", "RunPeriod", "Environment", and "Annual".
class	Class name for meter output. All possible values: "Output:Meter", "Output:Meter:MeterFileOnly", "Output:Meter:Cumulative", and "Output:Meter:Cumulative:MeterFileOnly". Default: "Output:Meter".

Value

A [data.table](#) with 5 columns with an additional attribute named eplus_version extracted from the original RddFile and MddFile:

- id: Integer type. Used to distinguish each object definition.
- class: Character type. Class names, e.g. Output:Variable and Output:Meter.
- index: Integer type. Field indices.
- field: Character type. Field names.
- value: Character type. The value of each field to be added.

Examples

```

## Not run:
# read an example distributed with eplusr
path_idf <- system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr")
idf <- read_idf(path_idf)

# run Design-Day-Only simulation silently
job <- idf$run(NULL, tempdir(), echo = FALSE)

# read RDD and MDD
rdd <- job$read_rdd()
mdd <- job$read_mdd()

# perform subsetting on the variables
# e.g.:
rdd_sub <- rdd[grepl("Site", variable)]
mdd_sub <- mdd[grepl("Electricity", variable)]

# use newly added helper `rdd_to_load()` and `mdd_to_load()` and `$load()` to
# add `Output:Variable` and `Output:Meter*`
idf$load(rdd_to_load(rdd_sub))
idf$load(mdd_to_load(mdd_sub))

# default `Key Value` is `*` and `Reporting Frequency` is `Timestep`
# can overwrite using `key_value` and `reporting_frequency` arg
rdd_to_load(rdd_sub, key_value = "Environment", reporting_frequency = "hourly")

# if input has column `key_value`, default is to use it, unless `key_value` is
# explicitly specified
rdd_to_load(rdd_sub[, key_value := "Environment"])
rdd_to_load(rdd_sub[, key_value := "Environment"], key_value = "*")

# `reporting_frequency` arg works in the same way as `key_value` arg, i.e.:
# if input has column `reporting_frequency`, use it, unless
# `reporting_frequency` is explicitly specified
rdd_to_load(rdd_sub[, reporting_frequency := "monthly"])
rdd_to_load(rdd_sub[, reporting_frequency := "monthly"], reporting_frequency = "detailed")

# if input has column `key_value`, default is to use it, unless `key_value` is
# explicitly specified
rdd_to_load(rdd_sub[, key_value := "Environment"])
rdd_to_load(rdd_sub[, key_value := "Environment"], key_value = "*")

# meter class can be further specified using `class` arg
mdd_to_load(mdd_sub, class = "Output:Meter:MeterFileOnly")

## End(Not run)

```

Description

read_epw() parses an EPW file and returns an Epw object. The parsing process is extremely inspired by [EnergyPlus/WeatherManager.cc] with some simplifications. For more details on Epw, please see [Epw](#) class.

Usage

```
read_epw(path, warning = FALSE)
```

Arguments

path	A path of an EnergyPlus EPW file.
warning	If TRUE, warnings are given if any missing data, out of range data and redundant data is found. Default: FALSE. All these data can be also retrieved using methods in Epw class.

Value

An Epw object.

Author(s)

Hongyuan Jia

See Also

[Epw](#) class

Examples

```
## Not run:
# read an EPW file from EnergyPlus v8.8 installation folder
if (is_avail_eplus(8.8)) {
  path_epw <- file.path(
    eplus_config(8.8)$dir,
    "WeatherData",
    "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"
  )
  read_epw(path_epw)
}

# read an EPW file from EnergyPlus website
path_base <- "https://energyplus.net/weather-download"
path_region <- "north_and_central_america_wmo_region_4/USA/CA"
path_file <- "USA_CA_San.Francisco.Intl.AP.724940_TMY3/USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"
path_epw <- file.path(path_base, path_region, path_file)
read_epw(path_epw)

## End(Not run)
```

read_err	<i>Read an EnergyPlus Simulation Error File</i>
----------	---

Description

read_err() takes a file path of EnergyPlus simulation error file, usually with an extension .err, parses it and returns an ErrFile object.

Usage

```
read_err(path)
```

Arguments

path a file path of EnergyPlus simulation error file, usually with an extension .err.

Details

Basically, an ErrFile object is a [data.table](#) with 6 columns and 6 additional attributes:

6 Columns:

- index: Integer. Index of messages.
- envir_index: Integer. Index of simulation environments.
- envir: Character. Names of simulation environments.
- level_index: Integer. Index for each severe level.
- level: Character. Name of severe levels. Possible values: Info, Warning, Severe, and etc.
- message: Character. Error messages.

6 Attributes:

- path: A single string. The path of input file.
- eplus_version: A [numeric_version](#) object. The version of EnergyPlus used during the simulation.
- eplus_build: A single string. The build tag of EnergyPlus used during the simulation.
- datetime: A DateTime (POSIXct). The time when the simulation started.
- idd_version: A [numeric_version](#). The version of IDD used during the simulation.
- successful: TRUE when the simulation ended successfully, and FALSE otherwise.
- terminated: TRUE when the simulation was terminated, and FALSE otherwise.

Value

An ErrFile object.

Examples

```
## Not run:
# run simulation and get the err file
idf_name <- "1ZoneUncontrolled.idf"
epw_name <- "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"
idf_path <- file.path(eplus_config(8.8)$dir, "ExampleFiles", idf_name)
epw_path <- file.path(eplus_config(8.8)$dir, "WeatherData", epw_name)
job <- eplus_job(idf_path, epw_path)
job$run(dir = tempdir())

# read the err file
read_err(job$locate_output(".err"))

## End(Not run)
```

read_idf

Read an EnergyPlus Input Data File (IDF)

Description

read_idf takes an EnergyPlus Input Data File (IDF) as input and returns an `Idf` object. For more details on `Idf` object, please see [Idf](#) class.

Usage

```
read_idf(path, idd = NULL)
```

Arguments

path	Either a path, a connection, or literal data (either a single string or a raw vector) to an EnergyPlus Input Data File (IDF). If a file path, that file usually has a extension <code>.idf</code> .
idd	Any acceptable input of use_idd() . If <code>NULL</code> , which is the default, the version of IDF will be passed to use_idd() . If the input is an <code>.ddy</code> file which does not have a version field, the latest version of Idf cached will be used.

Details

Currently, `Imf` file is not fully supported. All `EpMacro` lines will be treated as normal comments of the nearest downwards object. If input is an `Imf` file, a warning will be given during parsing. It is recommended to convert the `Imf` file to an `Idf` file and use [ParametricJob](#) class to conduct parametric analysis.

Value

An [Idf](#) object.

Author(s)

Hongyuan Jia

See Also

[Idf](#) class for modifying EnergyPlus model. [use_idd\(\)](#) and [download_idd\(\)](#) for downloading and parsing EnergyPlus IDD file. [use_eplus\(\)](#) for configuring which version of EnergyPlus to use.

Examples

```
## Not run:
# example model shipped with eplusr from EnergyPlus v8.8
idf_path <- system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr") # v8.8

# if neither EnergyPlus v8.8 nor Idd v8.8 was found, error will occur
# if EnergyPlus v8.8 is found but Idd v8.8 was not, `Energy+.idd` in EnergyPlus
# installation folder will be used for parsing
# if Idd v8.8 is found, it will be used automatically
is_avail_eplus(8.8)
is_avail_idd(8.8)

read_idf(idf_path)

# argument `idd` can be specified explicitly using `use_idd()`
read_idf(idf_path, idd = use_idd(8.8))

# you can set `download` argument to "auto" in `use_idd()` if you want to
# automatically download corresponding IDD file when necessary
read_idf(idf_path, use_idd(8.8, download = "auto"))

# Besides use a path to an IDF file, you can also provide IDF in literal
# string format
idf_string <-
  "
  Version, 8.8;
  Building,
    Building;           !- Name
  "

read_idf(idf_string, use_idd(8.8, download = "auto"))

## End(Not run)
```

read_rdd

Read an EnergyPlus Report Data Dictionary File

Description

`read_rdd()` takes a file path of EnergyPlus Report Data Dictionary (RDD) file, parses it and returns a `RddFile` object. `read_mdd()` takes a file path of EnergyPlus Meter Data Dictionary (MDD) file, parses it and returns a `MddFile` object.

Usage

```
read_rdd(path)
```

```
read_mdd(path)
```

Arguments

path For `read_rdd()`, a file path of EnergyPlus EnergyPlus Report Data Dictionary file with an extension `.rdd`. For `read_mdd()`, a file path of EnergyPlus EnergyPlus Meter Data Dictionary file with an extension `.mdd`

Details

Basically, a `RddFile` and `MddFile` object is a [data.table](#) with 5 columns and 3 additional attributes:
5 Columns:

*`index`: Integer. Index of each variable.

- `reported_time_step`: Character. Reported time step for the variables. Possible value: Zone and HVAC.
- `report_type`: Character. Report types. Possible value: Average, Sum and Meter. Note that Meter is only for MDD file. All variables will have `report_type` being Meter.
- `variable`: Character. Report variable names.
- `units`: Character. Units of reported values. NA if report values do not have units.

3 Attributes:

- `eplus_version`: A [numeric_version](#) object. The version of EnergyPlus used during the simulation.
- `eplus_build`: A single string. The build tag of EnergyPlus used during the simulation.
- `datetime`: A `DateTime` (`POSIXct`). The time when the simulation started.

Value

For `read_rdd()`, an `RddFile` object. For `read_mdd()`, a `MddFile` object.

Author(s)

Hongyuan Jia

Examples

```
## Not run:
# run simulation and get the err file
idf_name <- "1ZoneUncontrolled.idf"
epw_name <- "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"
idf_path <- file.path(eplus_config(8.8)$dir, "ExampleFiles", idf_name)
epw_path <- file.path(eplus_config(8.8)$dir, "WeatherData", epw_name)
job <- eplus_job(idf_path, epw_path)
job$run(dir = tempdir())
```

```
# read the err file
read_rdd(job$locate_output(".rdd"))
read_mdd(job$locate_output(".mdd"))

## End(Not run)
```

run_idf

Run simulations of EnergyPlus models.

Description

run_idf() is a wrapper of EnergyPlus command line interface which enables to run EnergyPlus model with different options.

Usage

```
run_idf(
  model,
  weather,
  output_dir,
  design_day = FALSE,
  annual = FALSE,
  expand_obj = TRUE,
  wait = TRUE,
  echo = TRUE,
  eplus = NULL
)

run_multi(
  model,
  weather,
  output_dir,
  design_day = FALSE,
  annual = FALSE,
  wait = TRUE,
  echo = TRUE,
  eplus = NULL
)
```

Arguments

model	A path (for run_idf()) or a vector of paths (for run_multi()) of EnergyPlus IDF or IMF files.
weather	A path (for run_idf()) or a vector of paths (for run_multi()) of EnergyPlus EPW weather files. For run_multi(), weather can also be a single EPW file path. In this case, that weather will be used for all simulations; otherwise, model and weather should have the same length.

output_dir	Output directory path (for run_idf()) or paths (for run_multi()). If NULL, the directory of input model is used. For run_multi(), output_dir, if not NULL, should have the same length as model. Any duplicated combination of model and output_dir is prohibited.
design_day	Force design-day-only simulation. Default: FALSE.
annual	Force design-day-only simulation. Default: FALSE.
expand_obj	Whether to run ExpandObject preprocessor before simulation. Default: TRUE.
wait	If TRUE, R will hang on and wait all EnergyPlus simulations finish. If FALSE, all EnergyPlus simulations are run in the background. and a <code>processx::process</code> object is returned. Note that, if FALSE, R is <i>not blocked</i> even when echo is TRUE. Default: TRUE.
echo	Only applicable when wait is TRUE. Whether to show standard output and error from EnergyPlus command line interface for run_idf() and simulation status for run_multi().Default: TRUE.
eplus	An acceptable input (for run_idf()) or inputs (for run_multi()) of <code>use_eplus()</code> and <code>eplus_config()</code> . If NULL, which is the default, the version of EnergyPlus to use is determined by the version of input model. For run_multi(), eplus, if not NULL, should have the same length as model.

Details

run_multi() provides the functionality of running multiple models in parallel.

run_idf() and run_multi() currently only support EnergyPlus v8.3 and above. This is because eplusr uses EnergyPlus command line interface which is a new feature as of EnergyPlus v8.3.

For run_idf(), a named list will be returned:

- idf: The path of IDF file
- epw: The path of EPW file
- exit_status: The exit code of the process if it has finished and NULL otherwise. Always being NULL if wait is FALSE, but you can manually get the exit code using the process object, i.e. `process$get_exit_status()` after simulation *completed*.
- start_time: When the EnergyPlus process started.
- end_time: When the EnergyPlus process stopped. All being NULL if wait is FALSE, but you can manually check EnergyPlus stdout to get the simulation time
- output_dir: The simulation output directory
- energyplus: The path of EnergyPlus executable
- stdout: All standard output from EnergyPlus. Always being NULL if wait is FALSE, but you can manually get all standard output using `process$get_result()`, where process is the `processx::process` object stored in returned element process.
- stderr: All standard error from EnergyPlus. Always being NULL if wait is FALSE, but you can manually get all standard output using `process$get_result()`, where process is the `processx::process` object stored in returned element process.
- process: A `processx::process` object of current EnergyPlus simulation

For `run_multi()`, if `wait` is `TRUE`, a `data.table` contains all data (excluding process) with same column names as above, and also another two columns:

- `index`: The index of simulation
- `status`: The status of simulation. Should be one of below:
 - `"completed"`: the simulation job is completed successfully.
 - `"failed"`: the simulation job ended with error.
 - `"terminated"`: the simulation job started but was terminated.
 - `"cancelled"`: the simulation job was cancelled, i.e. did not start at all.

For `run_multi()`, if `wait` is `FALSE`, a `r_process` object of background R process which handles all simulation jobs is returned. You can check if the jobs are completed using `$is_alive()` and get the final `data.table` using `$get_result()`.

It is suggested to run simulations using `EplusJob` class and `ParametricJob` class, which provide much more detailed controls on the simulation and also methods to extract simulation outputs.

Value

A list for `run_idf()`. For `run_multi()`, a `data.table` if `wait` is `TRUE` or a `process` if `wait` is `FALSE`.

Examples

```
## Not run:
idf_path <- system.file("extdata/1ZoneUncontrolled.idf", package = "eplusr")

if (is_avail_eplus(8.8)) {
  # run a single model
  epw_path <- file.path(
    eplus_config(8.8)$dir,
    "WeatherData",
    "USA_CA_San.Francisco.Intl.AP.724940_TMY3.epw"
  )

  run_idf(idf_path, epw_path, output_dir = tempdir())

  # run multiple model in parallel
  idf_paths <- file.path(eplus_config(8.8)$dir, "ExampleFiles",
```

```

    c("1ZoneUncontrolled.idf", "1ZoneUncontrolledFourAlgorithms.idf")
  )
  epw_paths <- rep(epw_path, times = 2L)
  output_dirs <- file.path(tempdir(), tools::file_path_sans_ext(basename(idf_paths)))
  run_multi(idf_paths, epw_paths, output_dir = output_dirs)
}

## End(Not run)

```

 transition

Perform version transition of EnergyPlus model

Description

transition() takes an [Idf](#) object or a path of IDF file and a target version, performs version transitions and returns an [Idf](#) object of specified version.

Usage

```
transition(idf, ver, keep_all = FALSE, save = FALSE, dir = NULL)
```

Arguments

idf	An Idf object or a path of IDF file.
ver	A valid EnergyPlus version, e.g. 9, 8.8, or "8.8.0".
keep_all	If TRUE, a list will be return which contains all Idf objects of intermediate versions. The list will be named using first two number of that version, e.g. 8.1, 8.2. If FALSE, only the Idf object of the version specified by ver will be returned. Default: FALSE.
save	If TRUE, the models will be saved into specified directory. Default: FALSE.
dir	Only applicable when save is TRUE. The directory to save the new IDF files. If the directory does not exist, it will be created before save. If NULL, the directory of input Idf object or IDF file will be used. Default: NULL.

Value

An [Idf](#) object if keep_all is FALSE or a list of [Idf](#) objects if keep_all is TRUE.

Examples

```
## Not run:
if (any(avail_eplus()) > 7.2) {
  # create an empty IDF
  idf <- empty_idf(7.2)

  # convert it from v7.2 to the latest EnergyPlus installed
  transition(idf, max(avail_eplus()))

  # convert it from v7.2 to the latest EnergyPlus installed and keep all
  # intermediate versions
  transition(idf, max(avail_eplus()), keep_all = TRUE)

  # convert it from v7.2 to the latest EnergyPlus installed and keep all
  # intermediate versions and save all them
  idf$save(tempfile(fileext = ".idf"))
  transition(idf, max(avail_eplus()), keep_all = TRUE,
            save = TRUE, dir = tempdir()
  )
}

## End(Not run)
```

use_eplus

Configure which version of EnergyPlus to use

Description

Configure which version of EnergyPlus to use

Usage

use_eplus(eplus)

eplus_config(ver)

avail_eplus()

is_avail_eplus(ver)

Arguments

eplus An acceptable EnergyPlus version or an EnergyPlus installation path.

ver An acceptable EnergyPlus version.

Details

use_eplus() adds an EnergyPlus version into the EnergyPlus version cache in eplusr. That cache will be used to get corresponding Idd object when parsing IDF files and call corresponding EnergyPlus to run models.

eplus_config() returns the a list of configure data of specified version of EnergyPlus. If no data found, an empty list will be returned.

avail_eplus() returns all versions of available EnergyPlus.

is_avail_eplus() checks if the specified version of EnergyPlus is available or not.

Value

- For use_eplus() and eplus_config(), an (invisible for use_eplus()) list of three contains EnergyPlus version, directory and EnergyPlus executable. version of EnergyPlus;
- For avail_eplus(), a **numeric_version** vector or NULL if no available EnergyPlus is found;
- For is_avis_avail_eplus(), a scalar logical vector.

Examples

```
## Not run:
# add specific version of EnergyPlus
use_eplus(8.9)
use_eplus("8.8.0")

# get configure data of specific EnergyPlus version if available
eplus_config(8.6)

## End(Not run)

# get all versions of available EnergyPlus
avail_eplus()

# check if specific version of EnergyPlus is available
is_avail_eplus(8.5)
is_avail_eplus(8.8)
```

use_idd

Use a specific EnergyPlus Input Data Dictionary (IDD) file

Description

Use a specific EnergyPlus Input Data Dictionary (IDD) file

Usage

```

use_idd(idd, download = FALSE)

download_idd(ver = "latest", dir = ".")

avail_idd()

is_avail_idd(ver)

```

Arguments

idd	Either a path, a connection, or literal data (either a single string or a raw vector) to an EnergyPlus Input Data Dictionary (IDD) file, usually named as Energy+.idd, or a valid version of IDD, e.g. 8.9, "8.9.0".
download	If TRUE and argument idd, the IDD file will be downloaded from EnergyPlus GitHub Repository , and saved to <code>tempdir()</code> . It will be parsed after it is downloaded successfully. A special value of "auto" can be given, which will automatically download corresponding IDD file if the Idd object is currently not available. It is useful in case when you only want to edit an EnergyPlus Input Data File (IDF) directly but do not want to install whole EnergyPlus software. Default is FALSE.
ver	A valid EnergyPlus version, e.g. 8, 8.7, "8.7" or "8.7.0". For <code>download_idd()</code> , the special value "latest", which is default, means the latest version.
dir	A directory to indicate where to save the IDD file. Default: current working directory.

Details

`use_idd()` takes a valid version or a path of an EnergyPlus Input Data Dictionary (IDD) file, usually named "Energy+.idd" and return an Idd object. For details on Idd class, please see [Idd](#).

`download_idd()` downloads specified version of EnergyPlus IDD file from [EnergyPlus GitHub Repository](#). It is useful in case where you only want to edit an EnergyPlus Input Data File (IDF) directly but do not want to install whole EnergyPlus software.

`avail_idd()` returns versions of all cached Idd object.

`is_avail_idd()` returns TRUE if input version of IDD file has been parsed and cached.

`eplusr` tries to detect all installed EnergyPlus in default installation locations when loading. If argument `idd` is a version, `eplusr` will try the follow ways sequentially to find corresponding IDD:

- The cached Idd object of that version
- "Energy+.idd" file distributed with EnergyPlus of that version (see [avail_eplus\(\)](#)).
- The "VX-Y-Z-Energy+.idd" file distributed along with IDFVersionUpdater from the latest EnergyPlus detected.

Value

- use_idd() returns an Idd object
- download_idd() returns an invisible integer 0 if succeed. Also an attribute named file which is the full path of the downloaded IDD file;
- avail_idd() returns a [numeric_version](#) vector or NULL if no available Idd object found.
- is_avail_idd() returns a single logical vector.

[Idd](#) Class for parsing, querying and making modifications to EnergyPlus IDD file

Examples

```
## Not run:
# get all available Idd version
avail_idd()

# check if specific version of Idd is available
is_avail_idd(8.5)

# download latest IDD file from EnergyPlus GitHub repo
str(download_idd("latest", tempdir()))

# use specific version of Idd
# only works if EnergyPlus v8.8 has been found or Idd v8.8 exists
use_idd(8.8)

# If Idd object is currently not avail_idd, automatically download IDD file
# from EnergyPlus GitHub repo and parse it
use_idd(8.8, download = "auto")

# now Idd v8.8 should be available
is_avail_idd(8.8)

# get specific version of parsed Idd object
use_idd(8.8)

avail_idd() # should contain "8.8.0"

## End(Not run)
```

version_updater	<i>Run IDFVersionUpdater to Update Model Versions</i>
-----------------	---

Description

version_updater() is a wrapper of IDFVersionUpdater preprocessor distributed with EnergyPlus. It takes a path of IDF file or an [Idf](#) object, a target version to update to and a directory to save the new models.

Usage

```
version_updater(idf, ver, dir = NULL, keep_all = FALSE)
```

Arguments

idf	An Idf object or a path of IDF file.
ver	A valid EnergyPlus version, e.g. 9, 8.8, or "8.8.0".
dir	The directory to save the new IDF files. If the directory does not exist, it will be created before save. If NULL, the directory of input Idf object or IDF file will be used. Default: NULL.
keep_all	If TRUE, a list will be return which contains all Idf objects of intermediate versions. The list will be named using first two number of that version, e.g. 8.1, 8.2. If FALSE, only the Idf object of the version specified by ver will be returned. Default: FALSE.

Details

An attribute named errors is attached which is a list of [ErrFiles](#) that contain all error messages from transition error (.VCpErr) files.

Value

An [Idf](#) object if keep_all is FALSE or a list of [Idf](#) objects if keep_all is TRUE. An attribute named errors is attached which contains all error messages from transition error (.VCpErr) files.
