Package 'genpathmox'

May 11, 2020

Title Generalized Pathmox Approach Segmentation Tree Analysis

Version 0.4

Description Provides a very interesting solution for
handling segmentation variables in complex statistical methodology. It
contains en extended version of the ``Pathmox'' algorithm (Lamberti, Sanchez
and Aluja,(2016)<doi:10.1002/asmb.2168>) in the context of
Partial Least Squares Path Modeling including the F-block
test (to detect the responsible latent endogenous equations of the
difference), the F-coefficient (to detect the path coefficients responsible
of the difference) and the ``invariance'' test (to realize a comparison
between the sub-models' latent variables). Furthermore, the package
contains a generalized version of the ``Pathmox'' algorithm to approach
different methodologies: linear regression and least absolute regression
models.

fibtele *Fibtele*

Description

Fibtele

Usage

```
fibtele
```

Format

A data frame with 147 observations on the following 35 variables. The first ten variables are segmentation variables. The rest of the variables refer to five latent concepts: 1) Image=Image, 2) Qual.spec=Specific Quality, 3) Qual.gen=Generic Quality, 4) Value=Value, 5) Satis=Satisfaction. Variables description

- Image: Generic students perception of ICT schools: (internationally recognized, ranges of courses, leader in research).

- Qual.spec: Perception about the achieved quality on the specific skills in the school.

- Qual.gen: Perception about achieved quality on the generic skills in the school (abilities in solving problem, communication skills).

- Value: The advantage or profit that the alumni may draw from the school degree (well paid job, motivated job, prospectives in improvement and promotion).

- Satis: Degree of alumni satisfaction about the formation in school respect to their actual work conditions.

Manifest variables description

- ima1MV:It is the best college to study IE

- ima2MV:It is internationally recognized

- ima3MV:It has a wide range of courses

- ima4MV:The Professors are good
- ima5MV:Facilities and equipment are good
- ima6MV:It is leader in research
- ima7MV:It is well regarded by the companies
- ima8MV:It is oriented to new needs and technologies
- quaf1MV:Basic skills
- quaf2MV:Specific Technic skills
- quaf3MV:Applied skills
- qutr1MV:Achieved abilities in solving problem
- qutr2MV:Training in business management
- qutr3MV:The written and oral communication skills
- qutr4MV:Planning and time management acquired
- qutr5MV:Team-work skills
- val1MV:It has allowed me to find a well paid job
- val2MV:I have good prospectives in improvement and promotion
- val3MV:It has allowed me to find a job that motivates me
- val4MV:The training received is the basis on which I will develope my career
- sat1MV:I am satisfied with the training received
- sat2MV:I am satisfied with my current situation
- sat3MV:I think I will have a good career
- sat4MV:What do you think is the prestige of your work

fibtelereg	*Fibtelereg*

Description

Fibtelereg dataset

Usage

fibtelereg

Format

A data frame with 147 observations on the following 18 variables. The first ten variables are segmentation variables. The rest of the variables refer to five variables 1) Image = Image, 2) Exp.spec = Specific Expectation, 3) Exp.gen = Generic Expectation, 4)Qual.spec = Specific Quality, 5) Qual.gen = Generic Quality, 6) Value = Value, 7) Satis = Satisfaction. Variables description

- Image: Generic students perception of ICT schools: (internationally recognized, ranges of courses, leader in research).
- Exp.spec: Specific Expectation on specific skills (technic or applied skills).
- Exp.gen: Generic Expectation on generic skills (abilities in problem solving, communication skills).
- Qual.spec: Perception about the achieved quality on the specific skills in the school.
- Qual.gen: Perception about achieved quality on the generic skills in the school (abilities in solving problem, communication skills).
- Value: The advantage or profit that the alumni may draw from the school degree (well paid job, motivated job, prospectives in improvement and promotion).
- Satis: Degree of alumni satisfaction about the formation in school respect to their actual work conditions.

invariance_test   *Invariance Test*

Description

The invariance test is a test that allows to verify the existence of common weights for the different local PLS-PM models identified by one or more segmentation variable.

Usage

```
invariance_test(x, nodes, inner, outer, mode, scheme, scaled)
```

Arguments

x	Matrix or data frame containing the manifest variables.
nodes	List of vectors. Each vector contains the position of the individual that belongs to a specific node.
inner	A square (lower triangular) boolean matrix representing the inner model (i.e. the path relationships between latent variables).
outer	list of vectors with column indices or column names from Data indicating the sets of manifest variables forming each block (i.e. which manifest variables correspond to each block).
mode	character vector indicating the type of measurement for each block. Possible values are: "A","B","newA","PLScore","PLScow". The length of mode must be equal to the length of outer.
scheme	string indicating the type of inner weighting scheme. Possible values are "centroid", "factorial", or "path".
scaled	whether manifest variables should be standardized. Only used when scaling = NULL. When (TRUE, data is scaled to standardized values (mean=0 and variance=1).

Details

The "x" refers to a matrix or a data.farme that contains all individuals used for the global PLS-PM estimation The "nodes" is a list of vectors. Each vector contains the position of the individual that belongs to a specific node. The position is idenfied by the number of row. For example, the row 4 corresponds to the individual 4 The other parameters are the classical parameter of the fucntion "plspm"

Value

An data.farme res. Basically a list with the following results:

chisq.statistic

	A Number; X^2 statistic
p.value	A Number; p-value
dfH0	A Number; degree of freedom null Hypotheis
dfH1	A Number; degree of freedom alternative Hypotheis
avg.weights	data frame of the common weights if they exist
test	data frame with summry information of the invariance test

pls.pathmox	*PATHMOX-PLS: Extended Segmentation Trees in Partial Least Squares Path Modeling*

Description

The function `pathmox.pls` calculates a binary segmentation tree in the context PLS-PM following the PATHMOX algorithm. The procedure can be resumed in the following way. It starts with the estimation of the global PLS Path Model at the root node. Then, using the segmentation variables, all possible binary splits of data are produced, and for each partition local models are calculated. Among all the splits, the best one is selected by means of the F-test comparing the inner models. This process is recursively applied for each child node. The stop criterion is based on the significance level of the p-value associated with the F statistic. Additionally, two stop parameters are also considered: the number of individuals in a node and the growing level of the depth of the tree. This function extends the pathmox algorithm introduced by Sanchez in 2009 including the two new test: the F-block test (to detect the responsible latent endogenous equations of the difference), the F-coefficient test (to detect the path coefficients responsible of the difference).The F-tests used in the split process are implemented following the classic lest square estimation. An implementation of the tests following the LAD regression also are proposed to overcome the parametric hypothesis of the F-test.

Usage

```
pls.pathmox(
  xpls,
  SVAR,
  signif,
  deep,
  method = "lm",
```

```
    size,
    X = NULL,
    n.node = 30,
    ...
)
```

Arguments

xpls	An object of class "plspm" returned by plspm.
SVAR	A data frame of factors contaning the segmentation variables.
signif	A numeric value indicating the significance threshold of the F-statistic. Must be a decimal number between 0 and 1.
deep	An integer indicating the depth level of the tree. Must be an integer greater than 1.
method	A string indicating the criterion used to calculate the the test can be equal to "lm" or "lad".
size	A numeric value indicating the minimum size of elements inside a node.
X	Optional dataset (matrix or data frame) used when argument dataset=NULL inside pls.
n.node	It is the minimum number of individuals to consider a candidate partition (30 by default).
...	Further arguments passed on to pls.pathmox.

Details

The argument xpls is object of class "plspm" returned by plspm.

The argument SVAR must be a data frame containing segmentation variables as factors. The number of rows in SVAR must be the same as the number of rows in the data used in pls.

The argument signif represent the p-value level takes as reference to stop the tree partitions.

The argument deep represent the depth level of the tree takes as reference to stop the tree partitions.

The argument method is a string contaning the criterion used to calculate the tests; if method="lm" the classic least square approach is used to perform the tests; if method="lad" the LAD (least absolute deviation regression) is used.

The argument size is defined as a decimal value (i.e. proportion of elements inside a node).

The argument n.node is the minimum number of individuals to consider a candidate partition. If the candidate split produces a partition where the number of individuals is less then n.node, the partition is not considered.

When the object pls does not contain a data matrix (i.e. pls$data=NULL), the user must provide the data matrix or data frame in X.

Value

An object of class "xtree.pls". Basically a list with the following results:

MOX	Data frame with the results of the segmentation tree

`root`	List of elements contanined in the root node
`terminal`	List of elements contanined in terminal nodes
`nodes`	List of elements contanined in all nodes: terminal and intermediate
`candidates`	List of data frames containing the candidate splits of each node partition
`Fg.r`	Data frame containing the results of the F-global test for each node partition
`Fb.r`	List of data frames containing the results of the F-block test for each node partition
`Fc.r`	A list of data frames containing the results of the F-coefficients test for each node partition
`model`	Informations about the internal paramenters

```

pls.treemodel	*PLS-PM results of terminal nodes from the Pathmox Segmentation Trees*

Description

Calculates basic PLS-PM results for the terminal nodes of PATHMOX trees

Usage

```
pls.treemodel(
  xpls,
  xtree,
  X = NULL,
  alpha = 0.05,
  terminal = TRUE,
  scaled = FALSE,
  label = FALSE,
  label.nodes = NULL,
  ...
)
```

Arguments

xpls	An object of class "plspm" returned by plspm.
xtree	An object of class "xtree.pls" returned by pls.pathmox.
X	Optional dataset (matrix or data frame) used when argument dataset=NULL inside xpls.
alpha	is numeric value indicating the significance threshold of the invariance test
terminal	is string, if equal to TRUE, just the terminal nodes are considered for the output reults. when it is equal to FALSE,the PLS-PM results are generated for all nodes of the tree
scaled	to standardize the latent variables or not
label	is a string. It is false for defect. If it is TRUE, label.nodes has to be fix.
label.nodes	is a vector with the name of the nodes. It is null for defect.
...	Further arguments passed on to pls.treemodel.

Details

The argument `xpls` must be the same used for calculating the `xtree` object. When the object `xpls` does not contain a data matrix (i.e. `pls$data=NULL`), the user must provide the data matrix or data frame in `X`.

The argument `xtree` is an object of class `"xtree.pls"` returned by `pls.pathmox`.

Value

An object of class `"treemodel.pls"`. Basically a list with the following results:

`inner`	Matrix of the inner relationship between latent variables of the PLS-PM model
`invariance.test`	
	A data frame containing the results of the invariance test
`weights`	Matrix of outer weights for each terminal node
`loadings`	Matrix of loadings for each terminal node
`paths`	Matrix of path coefficients for each terminal node
`r2`	Matrix of r-squared coefficients for each terminal node
`sign`	list of matrix with the significance for each terminal node

reg.pathmox   *PATHMOX-REG: Segmentation Trees in linaer and LAD regression*
                               model

Description

The function reg.pathmox calculates a binary segmentation tree in the context of linear regression following the PATHMOX algorithm. This function also generalizes the Pathmox algorithm introduced by Sanchez in 2009 to the context of linear and LAD regression.

Usage

```
reg.pathmox(formula, SVAR, signif, deep, method, size, data = NULL, ...)
```

Arguments

formula	An object of class "formula".
SVAR	A data frame of factors contaning the segmentation variables.
signif	A numeric value indicating the significance threshold of the F-statistic. Must be a decimal number between 0 and 1.
deep	An integer indicating the depth level of the tree. Must be an integer greater than 1.
method	A string indicating the criterion used to calculate the the test can be equal to "lm" or "lad" node.
size	A numeric value indicating the minimum size of elements inside a node.
data	an optional data frame.
...	Further arguments passed on to reg.pathmox.

Details

The argument formula is an object of class `"formula"` (or one that can be coerced to that class): a symbolic description of the model to be fitted.

The argument SVAR must be a data frame containing segmentation variables as factors. The number of rows in SVAR must be the same as the number of rows in the data

The argument signif represent the p-value level takes as reference to stop the tree partitions.

The argument deep represent the p-value level takes as reference to stop the tree partitions.

The argument method is a string contaning the criterion used to calculate the the test; if method="lm" the classic least square approach is used to perform the test; if method="lad" the lad (least absolute deviation) is used.

The argument size has defined as a decimal value (i.e. proportion of elements inside a node).

Value

An object of class `"xtree.reg"`. Basically a list with the following results:

MOX	Data frame with the results of the segmentation tree
root	element of contaning in the root node
terminal	element of contaning in the terminal nodes
nodes	element of contaning in all nodes terminal and intermediate
candidates	List of data frames containing the candidate splits of each node partition
Fg.r	Data frame containing the results of the F-global test for each node partition
Fc.r	A list of Data frames containing the results of the F-coefficients test for each node partition
model	Information about the internal paramenters

reg.treemodel *Regression results of terminal nodes from the Pathmox Segmentation Trees*

Description

Calculates basic regression results for the terminal nodes of Pathmox Segmentation Trees: liner regression and LAD trees

Usage

```
reg.treemodel(
  xtree.reg,
  terminal = TRUE,
  intercept = FALSE,
```

```
    label = FALSE,
    label.nodes = NULL,
    ...
)
```

Arguments

xtree.reg	An object of class "xtree.reg" returned by `reg.pathmox`.
terminal	is string, if equal to TRUE, just the terminal nodes are considered for the output reults. when it is equal to FALSE,the regression results are generated for all nodes of the tree
intercept	if equal to TRUE also the intercept is considered in the estimation
label	is a boolean. tI is false for defect. If it is TRUE, label.nodes has to be fix.
label.nodes	is a vector with the name of the nodes. It is null for defect.
...	Further arguments passed on to `reg.treemodel`.

Details

The argument xtree.reg is an object of class "xtree.reg" returned by `reg.pathmox`.

Value

An object of class "regtreemodel". Basically a list with the following results:

inner	Matrix of the inner relationship between latent variables of the PLS-PM model
method	A string containing the used method ("lm" or "lad"
coefficients	Matrix coefficients for each terminal node
Std.	Matrix of estandard deviation of coefficients for each terminal node
pval.coef	Matrix of p-value significance for each terminal node
r2	Matrix of r-squared coefficients for each terminal node

summary.xtree.pls   *Summary function for the Pathmox Segmentation Trees: PLS-PM*

Description

The function summary.xtree.pls returns the most important results obtained by the function pls.pathmox. In order, it provides the parameters algorithm (threshold significance,node size

limit",tree depth level and the method used for the split partition), the basic characteristics of the tree (deep and number of terminal nodes), the basic characteristics of the nodes and the F-global the F-block and F-coefficients results. For the test results the significance level is also indicated.

Usage

```
## S3 method for class 'xtree.pls'
summary(object, ...)
```

Arguments

object	An object of class "xtree.pls".
...	Further arguments are ignored.
