README: miWQS

Introduction

We have integrated WQS regression into the MI framework in a flexible $\mathcal{R}$ package called **miWQS** to meet a wide variety of needs (Figure 1). The data used in this package consist of a mixture of correlated components that share a common outcome while adjusting for other covariates. The correlated components in the set, X, may be complete or interval-censored between zero and low thresholds, or detection limits, that may be different across the components. The common outcome, y, may be modeled as binary, continuous, count-based, or rate-based and can be adjusted by the `family` and `offset` arguments of `estimate.wqs()`. Additional covariates, $\boldsymbol{Z}$, may be used in the bootstrap imputation and WQS models. If X is interval-censored, the choice of the imputation technique depends on the majority vote of BDL values among the components. When most chemicals have 80% of its values BDL, we suggest to use the BDLQ1 approach. When most chemicals have less than 80% of its values BDL, the user should perform Bayesian or bootstrapping multiple imputation. Previous literature suggests to ignore any chemicals that have greater than 80% of its values BDL. The **miWQS** package, though, still allows the user to perform single imputation. Regardless of the technique used, researchers may use the **miWQS** package in order to detect an association between the mixture and the outcome and to identify the important components in that mixture.

Installation

You can install the released version of miWQS from CRAN with:

```
install.packages("miWQS")
```

Example

Please see the vignette (that will soon be published) for a detailed step-by-step guide in using this package.
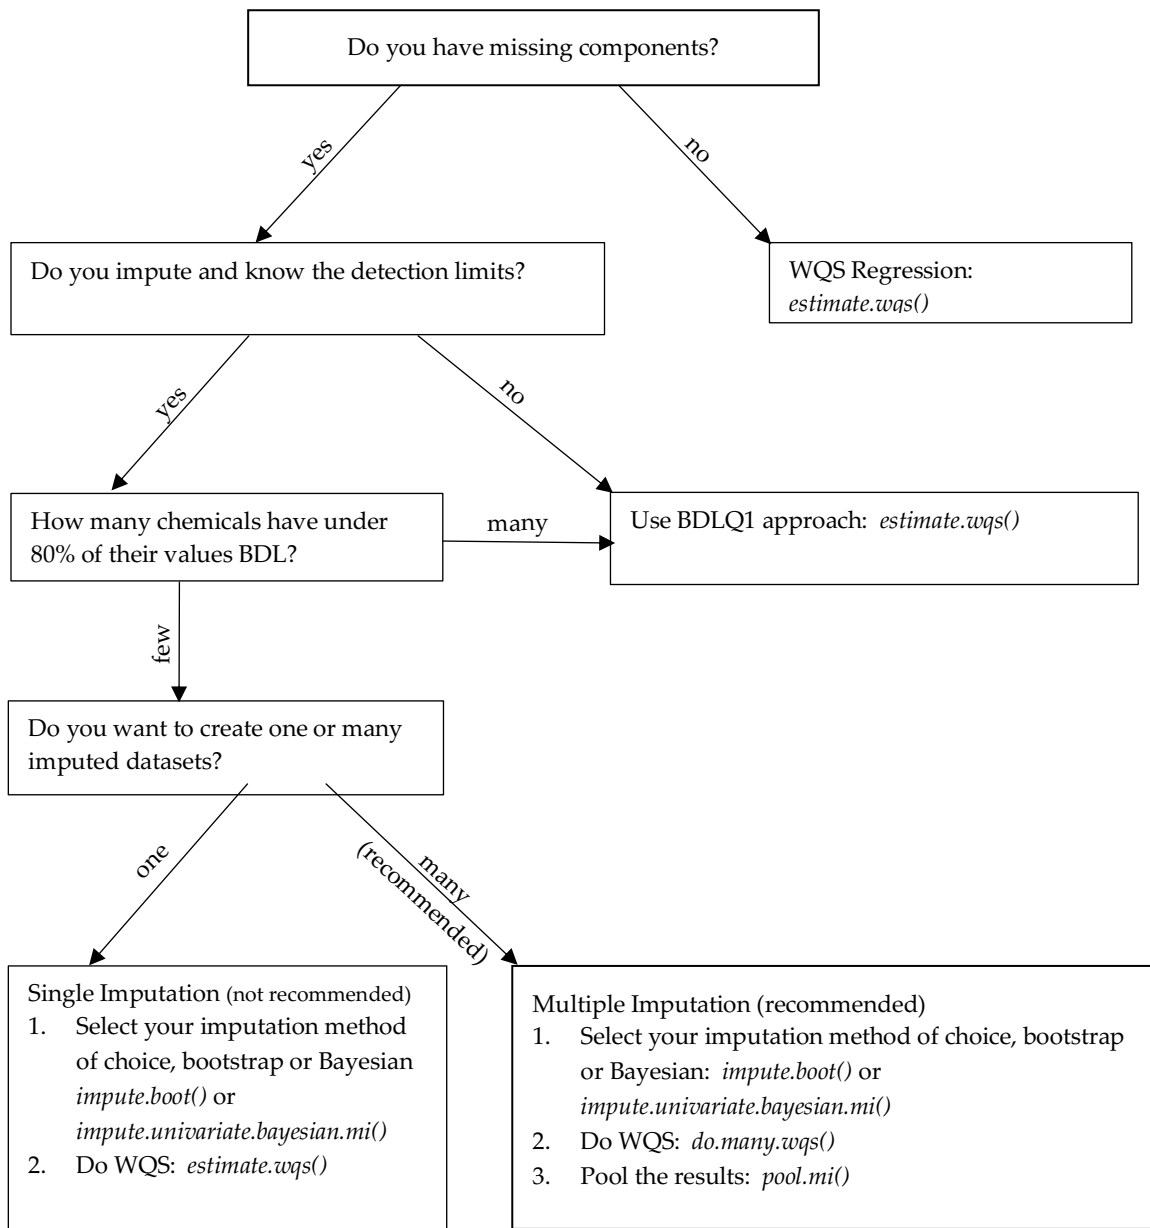

Figure 1: A decision tree to help researchers in using the miWQS package. The package is flexible and can meet a wide range of needs.
