

Package ‘partialOR’

February 20, 2015

Type Package

Title Partial Odds Ratio

Version 0.9

Date 2013-01-03

Author Vaclav Fidler and Nico Nagelkerke

Maintainer Vaclav Fidler <Vaclav.Fidler@gmail.com>

Description Computes Odds Ratio adjusted for a vector of possibly continuous covariates

License GPL (>= 2)

partialOR-package *PARTIAL ODDS RATIO ESTIMATION*

Description

Estimates odds ratio between two binary variables adjusted for a vector of covariates ("confounders"). It generalizes the Mantel-Haenszel procedure.

fitOR

*FITTING H- and F-MODELS***Description**

Fits the multinomial logistic regression models. See `partialOR()` for details.

Usage

```
fitOR(dd)
```

Arguments

dd	data frame with variables x,y,z1,...,zm
----	---

Value

fitH	details of the H-model fit as returned by the optimization procedure <code>optim()</code>
fitF	details of the F-model fit as returned by the function <code>summary.nnet()</code>
fit0	details of the null model, i.e. the model without covariates, as returned by <code>nnet()</code>

Author(s)

Vaclav.Fidler and Nico.Nagelkerke

Examples

```
## simulate example data
dd <- simData(50,2,1.5,123)
## fit the models
ff <- fitOR(dd)
## display parameter estimates of the H-model
ff$fitH$coefficients
```

partialOR

*PARTIAL ODDS RATIO ESTIMATION***Description**

Estimates odds ratio adjusted for a vector of covariates

Usage

```
partialOR(dd,ci=0.95)
```

Arguments

dd	Data frame with binary 0/1 response variables x,y and covariates z1,...,zm (in that order)
ci	Confidence level (default ci=0.95)

Details

`partialOR()` estimates the adjusted odds ratio $OR(X,Y | Z_1, \dots, Z_m)$ between two binary variables X and Y adjusted for a vector (Z_1, \dots, Z_m) of m numerical covariates ("confounders"). It is based on fitting a multinomial logistic regression model to the data. In this model the categorical response variable corresponds to the four possible outcomes of (X, Y) , namely $(0,0)$, $(0,1)$, $(1,0)$ and $(1,1)$. The program fits the null model (without covariates), the full F-model and the H-model with parameters restricted by the hypothesis of homogeneity of odds ratio's. The homogeneity hypothesis is tested by comparing the two models by the Likelihood Ratio test. The program reports OR estimates under the respective models, the standard errors of $\log(OR)$ and confidence intervals. Note: to include categorical covariates the user has to transform them into dummy variables.

Value

The program prints information about the convergence of the optimizer, the model deviances, the LR-test and the adjusted odds ratios. It calls the function `fitOR()` which, when called separately, returns detailed information on model fitting.

Examples

```
## simulate data from the H-model
dd <- simData(n=50, m=2, rr=1.5, rseed=123)
## estimate the OR
partialOR(dd)
```

Description

Prints the results of `fitOR()`.

Usage

```
reportOR(fit,dd,ci)
```

Arguments

fit	list containing output of <code>fitOR()</code>
dd	data frame used to fit the models
ci	confidence level (default 0.95)

Value

Prints the deviances of the null, F- and H-models, the LR-test, the odds ratio, standard error of log(OR) and confidence intervals based on parameters of the H- and F-models.

Examples

```
## generate data
dd <- simData(50,2,1.5,123)
## fit the models
fit <- fitOR(dd)
## report the results
reportOR(fit,dd,0.95)
```

simData*DATA SIMULATION***Description**

Simulates data to be used as an example for `partialOR`.

Usage

```
simData(n=50, m=2, rr=1.5, rseed = 123)
```

Arguments

n	number of independent observations
m	number of covariates
rr	common Odds Ratio
rseed	seed for the random number generator (default 123)

Details

The covariates are i.i.d. $N(0,1)$ variables.

Value

Data frame with n columns and m+2 variables x,y,z1,...,zm; x, y are 0/1 binary variables and z's are the covariates.

Examples

```
dd <- simData(50, 2, 1.5, rseed=123)
head(dd)
```
