# Package 'partitions' 

## October 21, 2019

Type Package
Title Additive Partitions of Integers
Version 1.9-22
Depends R (>=3.6.0)
Maintainer Robin K. S. Hankin <hankin. robin@gmail.com>
Imports gmp, polynom, sets
Description Additive partitions of integers. Enumerates the partitions, unequal partitions, and restricted partitions of an integer; the three corresponding partition functions are also given. Set partitions are now included.

```
    partitions-package Integer partitions
```

## Description

Routines to enumerate all partitions of an integer; includes restricted and unequal partitions.

## Details

This package comprises eight functions: $P(), Q(), R()$, and $S()$ give the number of partitions, unequal partitions, restricted partitions, and block partitions of an integer.
Functions parts(), diffparts(), restrictedparts(), and blockparts() enumerate these partitions.
Function conjugate() gives the conjugate of a partition and function durfee() gives the size of the Durfee square.
NB the emphasis in this package is terse, efficient C code. This means that there is a minimum of argument checking. For example, function conjugate() assumes that the partition is in standard form (ie nonincreasing); supplying a vector in nonstandard form will result in garbage being returned silently. Note that a block partition is not necessarily in standard form.

## Examples

```
parts(5)
diffparts(9)
restrictedparts(15,10)
P(10,give=TRUE)
Q(10,give=TRUE)
R(5,10)
```

## Description

Coercion to and from partitions

## Usage

\#\# S3 method for class 'partition'
as.matrix(x, ...)
as.partition(x, ...)

## Arguments

x
Object to be coerced
... Further arguments

Author(s)
Robin K. S. Hankin

## Examples

as.matrix(parts(5))
bin Sundry binary functionality

## Description

Utilities to convert things to binary

## Usage

tobin( $n$, len, check=TRUE)
todec(bin)
comptobin(comp, check=TRUE)
bintocomp(bin, use.C=TRUE, check=TRUE)

## Arguments

n
len Length of the binary vector returned by function tobin()
bin Binary: a vector of 0s and 1s
comp A composition
check Boolean, with default TRUE meaning to perform various checks
use.C Boolean, with default TRUE meaning to use $C$

## Details

These functions are not really intended for the end user; they are used in nextcomposition().

- Function tobin() converts integer $n$ to a binary string of length len
- Function $\operatorname{todec}()$ converts a binary string to decimal, so $\operatorname{todec}(\operatorname{tobin}(n, i))==n$, provided $i$ is big enough
- Function comptobin() converts a composition to binary
- Function bintocomp() converts a binary string to a composition

## Examples

tobin(10,5)
todec(tobin $(10,5))$
comptobin(c(1,1,4))
bintocomp(c(1, $1,0,0,1,1,1,1))$

```
conjugate Conjugate partitions and Durfee squares
```

## Description

Given a partition, provide its conjugate or Durfee square

## Usage

conjugate( $x$ )
durfee(x)

## Arguments

## x

Either a vector describing a partition, in standard form (ie nonincreasing); or a matrix whose columns are partitions in standard form

## Details

Conjugation is described in Andrews, and (eg) Hardy and Wright.
The conjugate of a partition may be calculated by taking its Ferrers diagram and considering the partition defined by columns instead of rows. This may be visualised by flipping the Ferrers diagram about the leading diagonal.
Essentially, conjugate () carries out $R$ idiom rev (cumsum(table (factor $(a[a>0], l e v e l s=m a x(a): 1)))$ ), but faster.

The "Durfee square" of a partition is defined on page 281 of Hardy and Wright. It is the largest square of nodes contained in the partition's Ferrers graph. Function durfee() returns the length of the side of the Durfee square, which Andrews denotes $d(\lambda)$. It is equivalent to R idiom function(a)\{sum(a>=1:length(a)) but faster.

## Value

Returns either a partition in standard form, or a matrix whose columns are partitions in standard form.

## Note

If argument $x$ is not nonincreasing, all bets are off: these functions will not work and will silently return garbage. Caveat emptor! (output from blockparts() is not necessarily non-increasing)

## Author(s)

Robin K. S. Hankin

## Examples

```
parts(5)
conjugate(parts(5))
restrictedparts(6,4)
conjugate(restrictedparts(6,4))
durfee(10:1)
# Suppose one wanted partitions of 8 with no part larger than 3:
conjugate(restrictedparts(8,3))
# (restrictedparts(8,3) splits 8 into at most 3 parts;
# so no part of the conjugate partition is larger than 3).
```

## nextpart Next partition

## Description

Given a partition, return the "next" one; or determine whether it is the last one.

```
Usage
    nextpart(part, check=TRUE)
islastpart(part)
    firstpart(n)
        nextdiffpart(part, check=TRUE)
islastdiffpart(part)
    firstdiffpart(n)
        nextrestrictedpart(part, check=TRUE)
islastrestrictedpart(part)
    firstrestrictedpart(n, m, include.zero=TRUE)
        nextblockpart(part, f, n=sum(part), include.fewer=FALSE, check=TRUE)
islastblockpart(part, f, n=NULL , include.fewer=FALSE)
    firstblockpart( f, n=NULL , include.fewer=FALSE)
        nextcomposition(comp, restricted, include.zero=TRUE, check=TRUE)
islastcomposition(comp, restricted, include.zero=TRUE)
    firstcomposition(n, m=NULL , include.zero=TRUE)
```

## Arguments

| part, comp | A partition or composition |
| :--- | :--- |
| check | Boolean, with default TRUE meaning to carry out various safety checks; the <br>  <br> next() functions use C calls which might crash the session with some inputs |
| $\mathrm{f}, \mathrm{n}$, include. fewer, m, include.zero |  |
| Other arguments as per the vectorized version |  |

## Details

These functions are intended to enumerate partitions one at a time, eliminating the need to store a huge matrix. This is useful for optimization over large domains and makes it possible to investigate larger partitions than is possible with the vectorized codes.

The idea is to use a first. . . () function to generate the first partition, then iterate using a next . . . () function, stopping when the islast...() function returns TRUE.

An example is given below, in which the "scrabble" problem is solved; note the small size of the sample space. More examples are given in the tests/aab.R file.

## Note

Functions nextpart() and nextdiffpart() require a vector of the right length: they require and return a partition padded with zeros. Functions nextrestrictedpart() and nextblockpart() work with partitions of the specified length. Function nextcomposition() truncates any zeros at the end of the composition. This behaviour is inherited from the C code.

In functions nextcomposition() and firstcomposition(), argument include.zero is ignored if restricted is FALSE.

I must say that the performance of these functions is terrible; they are much much slower than their vectorized equivalents. The magnitude of the difference is much larger than I expected. Heigh ho. Frankly you would better off working directly in C.

## Author(s)

Robin K. S. Hankin

parts

## Examples

```
# Do the optimization in scrabble vignette, one partition at a time:
# (but with a smaller letter bag)
scrabble <- c(a=9 , b=2 , c=2 , d=4 , e=12 , f=2 , g=3)
f <- function(a){prod(choose(scrabble,a))/choose(sum(scrabble),7)}
bestsofar <- 0
a <- firstblockpart(scrabble,7)
while(!islastpart(a)){
    jj <- f(a)
    if(jj>bestsofar){
        bestsofar <- jj
        bestpart <- a
    }
    a <- nextblockpart(a,scrabble)
}
```

P Number of partitions of an integer

## Description

Given an integer, $P()$ returns the number of additive partitions, $Q()$ returns the number of unequal partitions, and $R()$ returns the number of restricted partitions. Function $S()$ returns the number of block partitions.

## Usage

$\mathrm{P}(\mathrm{n}$, give = FALSE)
$\mathrm{Q}(\mathrm{n}$, give = FALSE)
$R(m, n$, include.zero = FALSE)
S(f, n = NULL, include.fewer = FALSE)

## Arguments

$\mathrm{n} \quad$ Integer whose partition number is desired. In function S() , the default of NULL means to return the number of partitions of any size
$m \quad$ In function $R()$, the order of the decomposition
give Boolean, with default FALSE meaning to return just $P(n)$ or $Q(n)$ and TRUE meaning to return $\mathrm{P}(1: n)$ or $\mathrm{Q}(1: n)$ (this option takes no extra computation)
include.zero In restrictedparts(), Boolean with default FALSE meaning to count only partitions of $n$ into exactly $m$ parts; and TRUE meaning to include partitions of $n$ into at most $m$ parts (because parts of zero are included)
include.fewer In function blockparts(), Boolean with default FALSE meaning to return partitions into exactly n and TRUE meaning to return partitions into at most n
$\mathrm{f} \quad$ In function $S()$, the stack vector

## Details

Functions P() and Q() use Euler's recursion formula. Function $R()$ enumerates the partitions using Hindenburg's method (see Andrews) and counts them until the recursion bottoms out.
Function S() finds the coefficient of $x^{n}$ in the generating function $\prod_{i=1}^{L} \sum_{j=0}^{f_{i}} x^{j}$, where $L$ is the length of $f$, using the polynom package.

All these functions return a double.

## Note

Functions $P()$ and $Q()$ use unsigned long long integers, a type which is system-dependent. For me, P() works for $n$ equal to or less than 416 , and Q () works for $n$ less than or equal to 792 . YMMV; none of the methods test for overflow, so use with care!

## Author(s)

Robin K. S. Hankin; S() is due to an anonymous JSS referee

## Examples

```
P(10,give=TRUE)
Q(10,give=TRUE)
R(10, 20,include.zero=FALSE)
R(10, 20,include.zero=TRUE)
S(1:4,5)
```

```
parts Enumerate the partitions of an integer
```

## Description

Given an integer, return a matrix whose columns enumerate various partitions.
Function parts() returns the unrestricted partitions; function diffparts() returns the unequal partitions; function restrictedparts() returns the restricted partitions; function blockparts() returns the partitions subject to specified maxima; and function compositions() returns all compositions of the argument.

## Usage

parts( $n$ )
diffparts(n)
restrictedparts(n, m, include.zero=TRUE, decreasing=TRUE)
blockparts(f, n=NULL, include.fewer=FALSE)
compositions( $n, m=N U L L, ~ i n c l u d e . z e r o=T R U E) ~$
multiset( $v, n=$ length( $v$ ))
mset(v)

## Arguments

n
$\mathrm{m} \quad$ In functions restrictedparts() and compositions(), the order of the partition
include.zero In functions restrictedparts() and compositions(), Boolean with default FALSE meaning to include only partitions of $n$ into exactly $m$ parts; and TRUE meaning to include partitions of $n$ into at most $m$ parts (because zero parts are included)
include.fewer In function blockparts(), Boolean with default FALSE meaning to return vectors whose sum is exactly n and TRUE meaning to return partitions whose sum is at most n
decreasing In restrictedparts(), Boolean with default TRUE meaning to return partitions whose parts are in decreasing order and FALSE meaning to return partitions in lexicographical order, as appearing in Hindenburg's algorithm. Note that setting to decreasing to FALSE has the effect of making conjugate() return garbage
f In function blockparts(), a vector of strictly positive integers that gives the maximal number of blocks; see details
v
In function multiset(), an integer vector representing a multiset. Argument $n$ is the size of the sample to be taken

## Details

- Function parts() uses the algorithm in Andrews. Function diffparts() uses a very similar algorithm that I have not seen elsewhere. These functions behave strangely if given an argument of zero.
- Function restrictedparts() uses the algorithm in Andrews, originally due to Hindenburg. For partitions into at most $m$ parts, the same Hindenburg's algorithm is used but with a start vector of $c(\operatorname{rep}(0, m-1), n)$.
If $m>n$, the partitions are padded with zeros.
- Function blockparts() enumerates the compositions of an integer subject to a maximum criterion: given vector $y=\left(y_{1}, \ldots, y_{n}\right)$ all sets of $a=\left(a_{1}, \ldots, a_{n}\right)$ satisfying $\sum_{i=1}^{p} a_{i}=n$ subject to $0 \leq a_{i} \leq y_{i}$ for all $i$ are given in lexicographical order. If argument y includes zero elements, these are treated consistently (ie a position with zero capacity).
If $n$ takes its default value of NULL, then the restriction $\sum_{i=1}^{p} a_{i}=n$ is relaxed (so that the numbers may sum to anything). Note that these solutions are not necessarily in standard form, so functions durfee() and conjugate() may fail.
- With a single argument, compositions(n) returns all $2^{n-1}$ ways of partitioning an integer; thus $4+1+1$ is distinct from $1+4+1$ or $1+1+4$.
With two arguments, compositions ( $\mathrm{n}, \mathrm{m}$ ) returns all nonnegative solutions to $x_{1}+\cdots+x_{m}=$ $n$.
This function is different from all the others in the package in that it is written in $R$; it is not clear that C would be any faster.
- Function multiset() returns all ways of ordering a multiset (mset() is a low-level helper function).

## Note

These vectorized functions return a matrix whose columns are the partitions. If this matrix is too large, consider enumerating the partitions individually using the functionality documented in nextpart.Rd.

One commonly encountered idiom is blockparts $(\operatorname{rep}(n, n), n)$, which is equivalent to compositions $(n, n)$ [Sloane's A001700].

restrictedparts(9,4,decreasing=TRUE)
blockparts(1:4)
blockparts(1:4,3)
blockparts(1:4,3,include.fewer=TRUE)
blockparts(c(4,3,3,2),5) # Knuth's example, pre-fascicle 3a, p16
compositions(4) # not the same as parts(4)
compositions(4,4)
# With 10 blocks, enumerate all partitions with maxima of 1:5 and minima
# of c(0,1,1,2,1):
a <- c(0,1,1,2,1)
sweep(blockparts(1:5-a,10-sum(a)),1,a,"+")
#Knuth's example:
multiset(c(1,2,2,3))
multiset(rep(4+1:3,1:3),3)
```

perms Enumerate the permutations of a vector

## Description

Given an integer $n$, return a matrix whose columns enumerate various permutations of $1: n$.
Function perms() returns all permutations in lexicographic order; function plainperms() returns all permutations by repeatedly exchanging adjacent pairs.

## Usage

perms( $n$ )
plainperms( $n$ )

## Arguments

n
Integer argument; permutations of $1: \mathrm{n}$ returned

## Note

Comments in the C code; algorithm lifted from 'fasc2b. pdf'.

```

```
    print.partition Print methods for partition objects and equivalence objects
```

## Description

A print method for partition objects, summary partition objects, and equivalence classes. Includes various configurable options

## Usage

```
## S3 method for class 'partition'
print(x, mat = getOption("matrixlike"), h = getOption("horiz"), ...)
## S3 method for class 'summary.partition'
print(x, ...)
## S3 method for class 'equivalence'
print(x, sep = getOption("separator"), ...)
```

## Arguments

x
mat Boolean, with TRUE meaning to print like a matrix, and any other value meaning to print without column names (which usually results in more compact appearance)
h
Boolean governing the orientation of the printed matrix, with TRUE meaning to print with the rows being the partitions and any other value (the default) meaning to print the transpose
sep Character vector, with special value of NULL interpreted as a comma; see examples section
... Further arguments provided for compatibility

## Examples

```
print(parts(5))
summary(parts(7))
listParts(3)
options(separator="")
listParts(5)
```

setparts Set partitions

## Description

Enumeration of set partitions

## Usage

setparts(x)
listParts(x,do.set=FALSE)
vec_to_set(vec)
vec_to_eq(vec)

## Arguments

X
If a vector of length 1 , the size of the set to be partitioned. If a vector of length greater than 1 , return all equivalence relations with equivalence classes with sizes of the elements of $x$. If a matrix, return all equivalence classes with sizes of the columns of $x$
do.set Boolean, with TRUE meaning to return the set partitions in terms of sets (as per sets package) and default FALSE meaning to present the result in terms of equivalence classes
vec An integer vector representing a set partition

## Details

A partition of a set $S=\{1, \ldots, n\}$ is a family of sets $T_{1}, \ldots, T_{k}$ satisfying

- $i \neq j \longrightarrow T_{i} \cap T_{j}=\emptyset$
- $\cup_{i=1}^{k} T_{k}=S$
- $T_{i} \neq \emptyset$ for $i=1, \ldots, k$

The induced equivalence relation has $i \sim j$ if and only if $i$ and $j$ belong to the same partition. Equivalence classes may be listed using listParts()
There are exactly fifteen ways to partition a set of four elements:

$$
\begin{aligned}
& (1234) \\
& (123)(4),(124)(3),(134)(2),(234)(1) \\
& (12)(34),(13)(24),(14)(23) \\
& (12)(3)(4),(13)(2)(4),(23)(1)(4),(24)(1)(3),(34)(1)(2) \\
& (1)(2)(3)(4)
\end{aligned}
$$

Note that $(12)(3)(4)$ is the same partition as, for example, $(3)(4)(21)$ as the equivalence relation is the same.
Consider partitions of a set $S$ of five elements (named 1, 2, 3, 4, 5) with sizes 2,2,1. These may be
enumerated as follows:

```
>u<- c(2,2,1)
> setparts(u)
[1,] 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 3 3 3
[2,] 2 2 3 1 1 1 2 2 3 2 2 3 1 1 1
[3,] 3 2 2 3 2 2 1 1 1 3 2 2 2 1 2
[4,] 2 3 2 2 3 2 3 2 2 1 1 1 2 2 1
[5,] 1 1 1 2 2 3 2 3 2 2 3 2 1 2 2
```

See how each column has two 1 s , two 2 s and one 3 . This is because the first and second classes have size two, and the third has size one.
The first partition, $x=c(1,2,3,2,1)$, is read "class 1 contains elements 1 and 5 (because the first and fifth element of $x$ is 1 ); class 2 contains elements 2 and 4 (because the second and fourth element of $x$ is 2 ); and class 3 contains element 3 (because the third element of $x$ is 3 )". Formally, class i has elements which ( $x==u[i]$ ).
You can change the print method by setting, eg, option(separator="").
Functions vec_to_set () and vec_to_eq() are low-level helper functions. These take an integer vector, typically a column of a matrix produced by setparts() and return their set representation.

## Value

Returns a matrix each of whose columns show a set partition; an object of class "partition". Type ?print. partition to see how to change the options for printing.

## Note

The clue package by Kurt Hornik contains functionality for partitions (specifically cl_meet () and cl_join()) which might be useful. Option do. set invokes functionality from the sets package by Meyer et al.

    # sets of different sizes
```

summary.partition Provides a summary of a partition

## Description

Provides a summary of an object of class partition: usually the first and last few partitions (columns)

## Usage

\#\# S3 method for class 'partition'
summary (object, ...)

## Arguments

object Partition
... Further arguments; see details section below

## Details

The ellipsis arguments are used to pass how many columns at the start and the end of the matrix are selected; this defaults to 10 .
The function is designed to behave as expected: if there is an argument named " $n$ ", then this is used. If there is no such argument, the first one is used.

## Value

A summary object is a list, comprising three elements:
shortened Boolean, with TRUE meaning that the middle section of the matrix is ommitted, and FALSE meaning that the entire matrix is returned because n is too big
$\mathrm{n} \quad$ Number of columns to return at the start and the end of the matrix
out Matrix returned: just the first and last n columns (if shortened is TRUE), or the whole matrix if not
