Package 'profmem'

January 30, 2018

Version 0.5.0 Title Simple Memory Profiling for R Imports utils Suggests R.rsp, markdown, microbenchmark VignetteBuilder R.rsp Description A simple and light-weight API for memory profiling of R expressions. The profiling is built on top of R's built-in memory profiler ('utils::Rprofmem()'), which records every memory allocation done by R (also native code). License LGPL (>= 2.1) LazyLoad TRUE URL https://github.com/HenrikBengtsson/profmem BugReports https://github.com/HenrikBengtsson/profmem/issues RoxygenNote 6.0.1 NeedsCompilation no Author Henrik Bengtsson [aut, cre, cph] Maintainer Henrik Bengtsson <henrikb@braju.com></henrikb@braju.com>

profmem
Index

2 profinem

Description

profmem() evaluates and memory profiles an R expression.

profmem_begin() starts the memory profiling of all the following R evaluations until profmem_end() is called.

profmem_suspend() suspends an active profiling until resumed by profmem_resume() or ended by profmem_end(). Calling profmem_begin() or profmem() will resume any suspended profiling. *Nested* resuming and suspending is *not* supported; it is a global state.

profmem_status() checks whether there is an active profmem session or not, and whether it is suspended or not.

profmem_depth() gets the number of nested / stacked profmem sessions.

Usage

```
profmem(expr, envir = parent.frame(), substitute = TRUE,
    threshold = getOption("profmem.threshold", 0L))

profmem_begin(threshold = getOption("profmem.threshold", 0L))

profmem_end()

profmem_suspend()

profmem_resume()

profmem_status()

profmem_depth()
```

Arguments

expr An R expression to be evaluated and profiled.

envir The environment in which the expression should be evaluated.

substitute Should expr be base::substitute():d or not.
threshold The smallest memory allocation (in bytes) to log.

Details

In order for memory profiling to work, R must have been *built* with memory profiling enabled. Function base::capabilities("profmem") will return TRUE of it is enabled, otherwise FALSE. If memory profiling is *not* supported, profmem() and profmem_begin() will produce an informative error. The pre-built R binaries on CRAN support memory profiling.

profinem 3

What is logged? The profmem() function uses utils::Rprofmem() for logging memory, which logs all memory *allocations* that are done via the R framework. Specifically, the logger is tied to allocVector3() part of R's native API. This means that nearly all memory allocations done in R are logged. *Neither* memory deallocations *nor* garbage collection events are logged. Furthermore, allocations done by non-R native libraries or R packages that use native code Calloc() / Free() for internal objects are also *not* logged.

Any memory events that would occur due to calling any of the **profmem** functions themselves will *not* be logged and *not* be part of the returned profile data (regardless whether memory profiling is active or not). This is intentional.

If a profinem profiling is already active, profinem() and profinem_begin() performs an *independent*, *nested* profiling, which has no affect on the already active one. When the active one completes, it will contain all memory events also collected by the nested profiling as if the nested one never occurred.

Profiling gathered by **profmem** *will* be corrupted if the code profiled calls utils::Rprofmem(), with the exception of such calls done via the **profmem** package itself.

Value

```
profmem() and profmem_end() returns the collected Rprofmem data.
profmem_begin() returns (invisibly) the number of nested profmem session currently active.
profmem_suspend() and profmem_resume() returns nothing.
profmem_status() returns "inactive", "active", or "suspended".
promem_depth() returns a non-negative integer.
```

Examples

```
if (capabilities("profmem")) {
## Memory profile an R expression
p <- profmem({</pre>
 x < - raw(1000)
 A \leftarrow matrix(rnorm(100), ncol = 10)
})
## Display the results
print(p)
## Total amount of memory allocation
total(p)
## Allocations greater than 1 kB
p2 <- subset(p, bytes > 1000)
print(p2)
## The expression is evaluated in the calling environment
str(x)
str(A)
}
```

4 readRprofmem

Read an Rprofmem log file	eadRprofmem
---------------------------	-------------

Description

Reads and parses an Rprofmem log file that was created by utils::Rprofmem().

Usage

```
readRprofmem(pathname, as = c("Rprofmem", "fixed", "raw"), drop = 0L, ...)
```

Arguments

as

pathname The Rprofmem log file to be read.

Specifies in what format data should be returned. If "raw", the line content of the file is returned as is (as a character vector). If "fixed", as "raw" but with missing newlines added to lines with empty stack calls (see Ref. 1). If "Rprofmem", the collected Rprofmem data is fully parsed into bytes and call

stack information.

drop Number of levels to drop from the top of the call stack.

... Not used

Value

An Rprofmem data.frame (or a character vector)
