

# Package ‘refund’

December 9, 2019

**Type** Package

**Title** Regression with Functional Data

**Version** 0.1-21

**Date** 2019-12-06

**Depends** R (>= 3.00.0)

**Imports** fda, Matrix, lattice, boot, mgcv (>= 1.8-23), MASS, magic, nlme, gamm4, lme4, RLRsim, splines, grpreg, ggplot2, stats, pbs, methods

**Suggests** RColorBrewer, reshape2, testthat

**Description** Methods for regression for functional data, including function-on-scalar, scalar-on-function, and function-on-function regression. Some of the functions are applicable to image data.

**License** GPL (>= 2)

**LazyLoad** yes

**LazyData** true

**Repository** CRAN

refund-package

*Regression with Functional Data***Description**

Methods for regression with functional data. Various approaches to regression with scalar responses and functional predictors are implemented by [pfr](#), [peer](#), [lpeer](#) and [fpcr](#). For regression with functional responses, see [pffr](#), [fosr](#), and [fosr2s](#).

**Details**

For a complete list of functions type `library(help=refund)`.

**Author(s)**

*Authors:* Jeff Goldsmith <jeff.goldsmith@columbia.edu>, Fabian Scheipl <fabian.scheipl@stat.uni-muenchen.de>, Lei Huang <huangracer@gmail.com>, Julia Wrobel <jw3134@cumc.columbia.edu>, Jonathan Gellar <jgellar1@jhu.edu>, Jaroslaw Harezlak, Mathew W. McLean <mathew.w.mclean@gmail.com>, Bruce Swihart <bswihart@jhsp.h.edu>, Luo Xiao <lxiao@jhsp.h.edu>, Ciprian Crainiceanu <ccrainic@jhsp.h.edu>, Philip Reiss <phil.reiss@nyumc.org>.

*Maintainer:* Lei Huang <huangracer@gmail.com>

af

*Construct an FGAM regression term***Description**

Defines a term  $\int_T F(X_i(t), t) dt$  for inclusion in an `mgcv::gam`-formula (or [bam](#) or [gamm](#) or `gamm4::gamm`) as constructed by [pfr](#), where  $F(x, t)$  is an unknown smooth bivariate function and  $X_i(t)$  is a functional predictor on the closed interval  $T$ . See [smooth.terms](#) for a list of bivariate basis and penalty options; the default is a tensor product basis with marginal cubic regression splines for estimating  $F(x, t)$ .

**Usage**

```
af(X, argvals = NULL, xind = NULL, basistype = c("te", "t2", "s"),
  integration = c("simpson", "trapezoidal", "riemann"), L = NULL,
  presmooth = NULL, presmooth.opts = NULL, Xrange = range(X, na.rm =
  T), Qtransform = FALSE, ...)
```

**Arguments**

X	functional predictors, typically expressed as an N by J matrix, where N is the number of columns and J is the number of evaluation points. May include missing/sparse functions, which are indicated by NA values. Alternatively, can be an object of class "fd"; see <a href="#">fd</a> .
argvals	indices of evaluation of X, i.e. $(t_{i1}, \dots, t_{iJ})$ for subject $i$ . May be entered as either a length-J vector, or as an N by J matrix. Indices may be unequally spaced. Entering as a matrix allows for different observations times for each subject. If NULL, defaults to an equally-spaced grid between 0 or 1 (or within $X\$basis\$rangeval$ if X is a fd object.)
xind	same as argvals. It will not be supported in the next version of refund.
basistype	defaults to "te", i.e. a tensor product spline to represent $F(x, t)$ . Alternatively, use "s" for bivariate basis functions (see <a href="#">s</a> ) or "t2" for an alternative parameterization of tensor product splines (see <a href="#">t2</a> )
integration	method used for numerical integration. Defaults to "simpson"'s rule for calculating entries in L. Alternatively and for non-equidistant grids, "trapezoidal" or "riemann".
L	an optional N by <code>ncol(argvals)</code> matrix giving the weights for the numerical integration over t. If present, overrides <code>integration</code> .
presmooth	string indicating the method to be used for preprocessing functional predictor prior to fitting. Options are <code>fpca.sc</code> , <code>fpca.face</code> , <code>fpca.ssvd</code> , <code>fpca.bspline</code> , and <code>fpca.interpolate</code> . Defaults to NULL indicating no preprocessing. See <a href="#">create.prep.func</a> .
presmooth.opts	list including options passed to preprocessing method <a href="#">create.prep.func</a> .
Xrange	numeric; range to use when specifying the marginal basis for the x-axis. It may be desired to increase this slightly over the default of <code>range(X)</code> if concerned about predicting for future observed curves that take values outside of <code>range(X)</code>
Qttransform	logical; should the functional be transformed using the empirical cdf and applying a quantile transformation on each column of X prior to fitting?
...	optional arguments for basis and penalization to be passed to the function indicated by <code>basistype</code> . These could include, for example, "bs", "k", "m", etc. See <a href="#">te</a> or <a href="#">s</a> for details.

**Value**

A list with the following entries:

call	a "call" to <code>te</code> (or <code>s</code> , <code>t2</code> ) using the appropriately constructed covariate and weight matrices.
argvals	the <code>argvals</code> argument supplied to <code>af</code>
L	the matrix of weights used for the integration
xindname	the name used for the functional predictor variable in the formula used by <code>mgcv</code>
tindname	the name used for <code>argvals</code> variable in the formula used by <code>mgcv</code>
Lname	the name used for the L variable in the formula used by <code>mgcv</code>

presmooth	the presmooth argument supplied to af
Xrange	the Xrange argument supplied to af
prep.func	a function that preprocesses data based on the preprocessing method specified in presmooth. See <a href="#">create.prep.func</a>

  zlim=zlms, xlab="t", ylab="p(rcst)")

vis.pfr(fit3, select=1, plot.type="contour")

## End(Not run)

```

---

af\_old

---

*Construct an FGAM regression term*

---

## Description

Defines a term  $\int_T F(X_i(t), t) dt$  for inclusion in an `mgcv::gam`-formula (or `bam` or `gamm` or `gamm4:::gamm`) as constructed by `fgam`, where  $F(x, t)$  is an unknown smooth bivariate function and  $X_i(t)$  is a functional predictor on the closed interval  $T$ . Defaults to a cubic tensor product B-spline with marginal second-order difference penalties for estimating  $F(x, t)$ . The functional predictor must be fully observed on a regular grid

## Usage

```

af_old(X, argvals = seq(0, 1, l = ncol(X)), xind = NULL,
  basistype = c("te", "t2", "s"), integration = c("simpson",
  "trapezoidal", "riemann"), L = NULL, splinepars = list(bs = "ps", k =
  c(min(ceiling(nrow(X)/5), 20), min(ceiling(ncol(X)/5), 20))), m =
  list(c(2, 2), c(2, 2))), presmooth = TRUE, Xrange = range(X),
  Qtransform = FALSE)

```

**Arguments**

X	an N by J=ncol(argvals) matrix of function evaluations $X_i(t_{i1}), \dots, X_i(t_{iJ}); i = 1, \dots, N$ .
argvals	matrix (or vector) of indices of evaluations of $X_i(t)$ ; i.e. a matrix with <i>i</i> th row $(t_{i1}, \dots, t_{iJ})$
xind	Same as argvals. It will discard this argument in the next version of refund.
basistype	defaults to "te", i.e. a tensor product spline to represent $F(x, t)$ Alternatively, use "s" for bivariate basis functions (see <a href="#">s</a> ) or "t2" for an alternative parameterization of tensor product splines (see <a href="#">t2</a> )
integration	method used for numerical integration. Defaults to "simpson"'s rule for calculating entries in L. Alternatively and for non-equidistant grids, "trapezoidal" or "riemann". "riemann" integration is always used if L is specified
L	optional weight matrix for the linear functional
splinepars	optional arguments specifying options for representing and penalizing the function $F(x, t)$ . Defaults to a cubic tensor product B-spline with marginal second-order difference penalties, i.e. <code>list(bs="ps", m=list(c(2, 2), c(2, 2)))</code> , see <a href="#">te</a> or <a href="#">s</a> for details
presmooth	logical; if true, the functional predictor is pre-smoothed prior to fitting; see <a href="#">smooth.basisPar</a>
Xrange	numeric; range to use when specifying the marginal basis for the <i>x</i> -axis. It may be desired to increase this slightly over the default of <code>range(X)</code> if concerned about predicting for future observed curves that take values outside of <code>range(X)</code>
Qtransform	logical; should the functional be transformed using the empirical cdf and applying a quantile transformation on each column of X prior to fitting? This ensures <code>Xrange=c(0, 1)</code> . If <code>Qtransform=TRUE</code> and <code>presmooth=TRUE</code> , presmoothing is done prior to transforming the functional predictor

**Value**

A list with the following entries:

1. call - a "call" to `te` (or `s`, `t2`) using the appropriately constructed covariate and weight matrices.
2. argvals - the `argvals` argument supplied to `af`
3. L the matrix of weights used for the integration `xindname` the name used for the functional predictor variable in the formula used by `mgcv`. `tindname` - the name used for `argvals` variable in the formula used by `mgcv` `Lname` - the name used for the L variable in the formula used by `mgcv` `presmooth` - the `presmooth` argument supplied to `af` `Qtransform` - the `Qtransform` argument supplied to `af` `Xrange` - the `Xrange` argument supplied to `af` `ecdflist` - a list containing one empirical cdf function from applying `ecdf` to each (possibly presmoothed) column of X. Only present if `Qtransform=TRUE` `Xfd` - an `fd` object from presmoothing the functional predictors using [smooth.basisPar](#). Only present if `presmooth=TRUE`. See [fd](#).

---

bayes\_fosr

*Bayesian Function-on-scalar regression*

---

## Description

Wrapper function that implements several approaches to Bayesian function- on-scalar regression. Currently handles real-valued response curves; models can include subject-level random effects in a multilevel framework. The residual curve error structure can be estimated using Bayesian FPCA or a Wishart prior. Model parameters can be estimated using a Gibbs sampler or variational Bayes.

## Usage

```
bayes_fosr(formula, data = NULL, est.method = "VB",
           cov.method = "FPCA", ...)
```

## Arguments

formula	a formula indicating the structure of the proposed model. Random intercepts are designated using <a href="#">re()</a> .
data	an optional data frame, list or environment containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which the function is called.
est.method	method used to estimate model parameters. Options are "VB", "Gibbs", and "GLS" with "VB" as default. Variational Bayes is a fast approximation to the full posterior and often provides good point estimates, but may be unreliable for inference. "GLS" doesn't do anything Bayesian – just fits an unpenalized GLS estimator for the specified model.
cov.method	method used to estimate the residual covariance structure. Options are "FPCA" and "Wishart", with default "FPCA"
...	additional arguments that are passed to individual fitting functions.

*Corrected confidence bands using functional principal components*

---

### Description

Uses iterated expectation and variances to obtain corrected estimates and inference for functional expansions.

### Usage

```
ccb.fpc(Y, argvals = NULL, nbasis = 10, pve = 0.99, n.boot = 100,
        simul = FALSE, sim.alpha = 0.95)
```

### Arguments

Y	matrix of observed functions for which estimates and covariance matrices are desired.
argvals	numeric; function argument.
nbasis	number of splines used in the estimation of the mean function and the bivariate smoothing of the covariance matrix
pve	proportion of variance explained used to choose the number of principal components to be included in the expansion.
n.boot	number of bootstrap iterations used to estimate the distribution of FPC decomposition objects.
simul	TRUE or FALSE, indicating whether critical values for simultaneous confidence intervals should be estimated
sim.alpha	alpha level of the simultaneous intervals.

### Details

To obtain corrected curve estimates and variances, this function accounts for uncertainty in FPC decomposition objects. Observed curves are resampled, and a FPC decomposition for each sample is constructed. A mixed-model framework is used to estimate curves and variances conditional on each decomposition, and iterated expectation and variances combines both model-based and decomposition-based uncertainty.

**Value**

Yhat	a matrix whose rows are the estimates of the curves in Y.
Yhat.boot	a list containing the estimated curves within each bootstrap iteration.
diag.var	diagonal elements of the covariance matrices for each estimated curve.
VarMats	a list containing the estimated covariance matrices for each curve in Y.
crit.val	estimated critical values for constructing simultaneous confidence intervals.

## End(Not run)

```

---

cd4 *Observed CD4 cell counts*

---

### Description

CD4 cell counts for 366 subjects between months -18 and 42 since seroconversion. Each subject's observations are contained in a single row.

### Format

A data frame made up of

**list("cd4")** A 366 x 61 matrix of CD4 cell counts.

A 366 x 61 matrix of CD4 cell counts.

### References

Goldsmith, J., Greven, S., and Crainiceanu, C. (2013). Corrected confidence bands for functional data using principal components. *Biometrics*, 69(1), 41–51.

---

cmdscale\_lanczos *Faster multi-dimensional scaling*

---

### Description

This is a modified version of `cmdscale` that uses the Lanczos procedure (`slanczos`) instead of `eigen`. Called by `smooth.construct.pco.smooth.spec`.

### Usage

```
cmdscale_lanczos(d, k = 2, eig = FALSE, add = FALSE, x.ret = FALSE)
```

**Arguments**

d	a distance structure as returned by <a href="#">dist</a> , or a full symmetric matrix of distances or dissimilarities.
k	the maximum dimension of the space which the data are to be represented in; must be in $\{1, 2, \dots, n-1\}$ .
eig	logical indicating whether eigenvalues should be returned.
add	logical indicating if the additive constant of Cailliez (1983) should be computed, and added to the non-diagonal dissimilarities such that the modified dissimilarities are Euclidean.
x.ret	indicates whether the doubly centred symmetric distance matrix should be returned.

**Value**

as [cmdscale](#)

**Author(s)**

David L Miller, based on code by R Core.

**References**

Cailliez, F. (1983). The analytical solution of the additive constant problem. *Psychometrika*, 48, 343-349.

**See Also**

[smooth.construct.pco.smooth.spec](#)

---

 coef.pffr

---

*Get estimated coefficients from a pffr fit*

---

**Description**

Returns estimated coefficient functions/surfaces  $\beta(t)$ ,  $\beta(s, t)$  and estimated smooth effects  $f(z)$ ,  $f(x, z)$  or  $f(x, z, t)$  and their point-wise estimated standard errors. Not implemented for smooths in more than 3 dimensions.

**Usage**

```
## S3 method for class 'pffr'
coef(object, raw = FALSE, se = TRUE, freq = FALSE,
      sandwich = FALSE, seWithMean = TRUE, n1 = 100, n2 = 40,
      n3 = 20, Ktt = NULL, ...)
```

**Arguments**

object	a fitted pffr-object
raw	logical, defaults to FALSE. If TRUE, the function simply returns object\$coefficients
se	logical, defaults to TRUE. Return estimated standard error of the estimates?
freq	logical, defaults to FALSE. If FALSE, use posterior variance object\$Vp for variability estimates, else use object\$Ve. See <a href="#">gamObject</a>
sandwich	logical, defaults to FALSE. Use a Sandwich-estimator for approximate variances? See Details. THIS IS AN EXPERIMENTAL FEATURE, USE A YOUR OWN RISK.
seWithMean	logical, defaults to TRUE. Include uncertainty about the intercept/overall mean in standard errors returned for smooth components?
n1	see below
n2	see below
n3	n1, n2, n3 give the number of gridpoints for 1-/2-/3-dimensional smooth terms used in the marginal equidistant grids over the range of the covariates at which the estimated effects are evaluated.
Ktt	(optional) an estimate of the covariance operator of the residual process $\epsilon_i(t) \sim N(0, K(t, t'))$ , evaluated on yind of object. If not supplied, this is estimated from the crossproduct matrices of the observed residual vectors. Only relevant for sandwich CIs.
...	other arguments, not used.

**Details**

The seWithMean-option corresponds to the "iterms"-option in [predict.gam](#). The sandwich-options works as follows: Assuming that the residual vectors  $\epsilon_i(t), i = 1, \dots, n$  are i.i.d. realizations of a mean zero Gaussian process with covariance  $K(t, t')$ , we can construct an estimator for  $K(t, t')$  from the  $n$  replicates of the observed residual vectors. The covariance matrix of the stacked observations  $\text{vec}(Y_i(t))$  is then given by a block-diagonal matrix with  $n$  copies of the estimated  $K(t, t')$  on the diagonal. This block-diagonal matrix is used to construct the "meat" of a sandwich covariance estimator, similar to Chen et al. (2012), see reference below.

**Value**

If raw==FALSE, a list containing

- pterms a matrix containing the parametric / non-functional coefficients (and, optionally, their se's)
- smterms a named list with one entry for each smooth term in the model. Each entry contains
  - coef a matrix giving the grid values over the covariates, the estimated effect (and, optionally, the se's). The first covariate varies the fastest.
  - x, y, z the unique gridpoints used to evaluate the smooth/coefficient function/coefficient surface
  - xlim, ylim, zlim the extent of the x/y/z-axes
  - xlab, ylab, zlab the names of the covariates for the x/y/z-axes

- dim the dimensionality of the effect
- main the label of the smooth term (a short label, same as the one used in `summary.pffr`)

---

coefboot.pffr

*Simple bootstrap CIs for pffr*

---

### Description

This function resamples observations in the data set to obtain approximate CIs for different terms and coefficient functions that correct for the effects of dependency and heteroskedasticity of the residuals along the index of the functional response, i.e., it aims for correct inference if the residuals along the index of the functional response are not i.i.d.

### Usage

```
coefboot.pffr(object, n1 = 100, n2 = 40, n3 = 20, B = 100,
  ncpus = getOption("boot.ncpus", 1), parallel = c("no", "multicore",
  "snow"), cl = NULL, conf = c(0.9, 0.95), type = "percent",
  method = c("resample", "residual", "residual.c"),
  showProgress = TRUE, ...)
```

### Arguments

object	a fitted <a href="#">pffr</a> -model
n1	see <a href="#">coef.pffr</a>
n2	see <a href="#">coef.pffr</a>
n3	see <a href="#">coef.pffr</a>
B	number of bootstrap replicates, defaults to (a measly) 100
ncpus	see <a href="#">boot</a> . Defaults to <code>getOption("boot.ncpus", 1L)</code> (like <code>boot</code> ).
parallel	see <a href="#">boot</a>
cl	see <a href="#">boot</a>

conf	desired levels of bootstrap CIs, defaults to 0.90 and 0.95
type	type of bootstrap interval, see <code>boot.ci</code> . Defaults to "percent" for percentile-based CIs.
method	either "resample" (default) to resample response trajectories, or "residual" to resample responses as fitted values plus residual trajectories or "residual.c" to resample responses as fitted values plus residual trajectories that are centered at zero for each gridpoint.
showProgress	TRUE/FALSE
...	not used

**Value**

a list with similar structure as the return value of `coef.pfr`, containing the original point estimates of the various terms along with their bootstrap CIs.

**Author(s)**

Fabian Scheipl

---

coefficients.pfr

*Extract coefficient functions from a fitted pfr-object*

---

**Description**

This function is used to extract a coefficient from a fitted 'pfr' model, in particular smooth functions resulting from including functional terms specified with `lf`, `af`, etc. It can also be used to extract smooths generated using `mgcv`'s `s`, `te`, or `t2`.

**Usage**

```
## S3 method for class 'pfr'
coefficients(object, select = 1, coords = NULL,
  n = NULL, se = ifelse(length(object$smooth) & select, TRUE, FALSE),
  seWithMean = FALSE, useVc = TRUE, Qtransform = FALSE, ...)

## S3 method for class 'pfr'
coef(object, select = 1, coords = NULL, n = NULL,
  se = ifelse(length(object$smooth) & select, TRUE, FALSE),
  seWithMean = FALSE, useVc = TRUE, Qtransform = FALSE, ...)
```

**Arguments**

object	return object from <code>pfr</code>
select	integer indicating the index of the desired smooth term in <code>object\$smooth</code> . Enter 0 to request the raw coefficients (i.e., <code>object\$coefficients</code> ) and standard errors (if <code>se==TRUE</code> ).

coords	named list indicating the desired coordinates where the coefficient function is to be evaluated. Names must match the argument names in <code>object\$smooth[[select]]\$term</code> . If NULL, uses <code>n</code> to generate equally-spaced coordinates.
n	integer vector indicating the number of equally spaced coordinates for each argument. If length 1, the same number is used for each argument. Otherwise, the length must match <code>object\$smooth[[select]]\$dim</code> .
se	if TRUE, returns pointwise standard error estimates. Defaults to FALSE if raw coefficients are being returned; otherwise TRUE.
seWithMean	if TRUE the standard errors include uncertainty about the overall mean; if FALSE, they relate purely to the centered smooth itself. Marra and Wood (2012) suggests that TRUE results in better coverage performance for GAMs.
useVc	if TRUE, standard errors are calculated using a covariance matrix that has been corrected for smoothing parameter uncertainty. This matrix will only be available under ML or REML smoothing.
Qtransform	For additive functional terms, TRUE indicates the coefficient should be extracted on the quantile-transformed scale, whereas FALSE indicates the scale of the original data. Note this is different from the <code>Qtransform</code> argument of <code>af</code> , which specifies the scale on which the term is fit.
...	these arguments are ignored

**Value**

a data frame containing the evaluation points, coefficient function values and optionally the SE's for the term indicated by `select`.

Marra, G and S.N. Wood (2012) Coverage Properties of Confidence Intervals for Generalized Additive Model Components. *Scandinavian Journal of Statistics*.

---

create.prep.func      *Construct a function for preprocessing functional predictors*

---

**Description**

Prior to using functions  $X$  as predictors in a scalar-on-function regression, it is often necessary to presmooth curves to remove measurement error or interpolate to a common grid. This function creates a function to do this preprocessing depending on the method specified.

**Usage**

```
create.prep.func(X, argvals = seq(0, 1, length = ncol(X)),
  method = c("fpca.sc", "fpca.face", "fpca.ssvd", "bspline",
    "interpolate"), options = NULL)
```

**Arguments**

X	an N by J=ncol(argvals) matrix of function evaluations $X_i(t_{i1}), \dots, X_i(t_{iJ}); i = 1, \dots, N$ . For FPCA-based processing methods, these functions are used to define the eigen decomposition used to preprocess current and future data (for example, in <a href="#">predict.pfr</a> )
argvals	matrix (or vector) of indices of evaluations of $X_i(t)$ ; i.e. a matrix with $i$ th row $(t_{i1}, \dots, t_{iJ})$
method	character string indicating the preprocessing method. Options are "fpca.sc", "fpca.face", "fpca.ssvd", "bspline", and "interpolate". The first three use the corresponding existing function; "bspline" uses an (unpenalized) cubic bspline smoother with nbasis basis functions; "interpolate" uses linear interpolation.
options	list of options passed to the preprocessing method; as an example, options for fpca.sc include pve, nbasis, and npc.

**Value**

a function that returns the preprocessed functional predictors, with arguments

newX	The functional predictors to process
argvals.	Indices of evaluation of newX
options.	Any options needed to preprocess the predictor functions

**Author(s)**

Jeff Goldsmith <ajg2202@cumc.columbia.edu>

**Description**

Fractional anisotropy (FA) tract profiles for the corpus callosum (cca) and the right corticospinal tract (rcst). Accompanying the tract profiles are the subject ID numbers, visit number, total number of scans, multiple sclerosis case status and Paced Auditory Serial Addition Test (pasat) score.

## Format

A data frame made up of

**cca** A 382 x 93 matrix of fractional anisotropy tract profiles from the corpus callosum;

**rcst** A 382 x 55 matrix of fractional anisotropy tract profiles from the right corticospinal tract;

**ID** Numeric vector of subject ID numbers;

**visit** Numeric vector of the subject-specific visit numbers;

**visit.time** Numeric vector of the subject-specific visit time, measured in days since first visit;

**Nscans** Numeric vector indicating the total number of visits for each subject;

**case** Numeric vector of multiple sclerosis case status: 0 - healthy control, 1 - MS case;

**sex** factor variable indicated subject's sex;

**pasat** Numeric vector containing the PASAT score at each visit.

## Details

If you use this data as an example in written work, please include the following acknowledgment: "The MRI/DTI data were collected at Johns Hopkins University and the Kennedy-Krieger Institute"

DTI2 uses mean diffusivity of the the corpus callosum rather than FA, and parallel diffusivity of the rcst rather than FA. Please see the documentation for DTI2.

---

DTI2

*Diffusion Tensor Imaging: more fractional anisotropy profiles and outcomes*

---

## Description

A diffusion tensor imaging dataset used in Swihart et al. (2012). Mean diffusivity profiles for the corpus callosum (cca) and parallel diffusivity for the right corticospinal tract (rcst). Accompanying the profiles are the subject ID numbers, visit number, and Paced Auditory Serial Addition Test (pasat) score. We thank Dr. Daniel Reich for making this dataset available.

**Format**

A data frame made up of

**cca** a 340 x 93 matrix of fractional anisotropy profiles from the corpus callosum;

**rcst** a 340 x 55 matrix of fractional anisotropy profiles from the right corticospinal tract;

**id** numeric vector of subject ID numbers;

**visit** numeric vector of the subject-specific visit numbers;

**pasat** numeric vector containing the PASAT score at each visit.

**Details**

If you use this data as an example in written work, please include the following acknowledgment: "The MRI/DTI data were collected at Johns Hopkins University and the Kennedy-Krieger Institute"

Note: DTI2 uses mean diffusivity of the the corpus callosum rather than fractional anisotropy (FA), and parallel diffusivity of the rcst rather than FA. Please see the documentation for DTI for more about the DTI dataset.

---

expand.call

*Return call with all possible arguments*

---

**Description**

Return a call in which all of the arguments which were supplied or have presets are specified by their full names and their supplied or default values.

**Usage**

```
expand.call(definition = NULL, call = sys.call(sys.parent(1)),
            expand.dots = TRUE)
```

**Arguments**

**definition** a function. See [match.call](#).

**call** an unevaluated call to the function specified by definition. See [match.call](#).

**expand.dots** logical. Should arguments matching ... in the call be included or left as a ... argument? See [match.call](#).

**Value**

An object of mode `"call"`.

**Author(s)**

Fabian Scheipl

**See Also**

[match.call](#)

---

fbps

*Sandwich smoother for matrix data*

---

**Description**

A fast bivariate  $P$ -spline method for smoothing matrix data.

**Usage**

```
fbps(data, subj = NULL, covariates = NULL, knots = 35,
      knots.option = "equally-spaced", periodicity = c(FALSE, FALSE),
      p = 3, m = 2, lambda = NULL, selection = "GCV",
      search.grid = T, search.length = 100, method = "L-BFGS-B",
      lower = -20, upper = 20, control = NULL)
```

**Arguments**

<code>data</code>	<code>n1</code> by <code>n2</code> data matrix without missing data
<code>subj</code>	vector of subject id (corresponding to the columns of data); defaults to <code>NULL</code>
<code>covariates</code>	list of two vectors of covariates of lengths <code>n1</code> and <code>n2</code> ; if <code>NULL</code> , then generates equidistant covariates
<code>knots</code>	list of two vectors of knots or number of equidistant knots for all dimensions; defaults to 35
<code>knots.option</code>	knot selection method; defaults to "equally-spaced"
<code>periodicity</code>	vector of two logical, indicating periodicity in the direction of row and column; defaults to <code>c(FALSE, FALSE)</code>
<code>p</code>	degrees of B-splines; defaults to 3
<code>m</code>	order of differencing penalty; defaults to 2
<code>lambda</code>	user-specified smoothing parameters; defaults to <code>NULL</code>
<code>selection</code>	selection of smoothing parameter; defaults to "GCV"
<code>search.grid</code>	logical; defaults to <code>TRUE</code> , if <code>FALSE</code> , uses <code>optim</code>
<code>search.length</code>	number of equidistant (log scale) smoothing parameter; defaults to 100
<code>method</code>	see <code>optim</code> ; defaults to <code>L-BFGS-B</code>
<code>lower, upper</code>	bounds for log smoothing parameter, passed to <code>optim</code> ; defaults are -20 and 20.
<code>control</code>	see <code>optim</code>

**Details**

The smoothing parameter can be user-specified; otherwise, the function uses grid searching method or `optim` for selecting the smoothing parameter.

**Value**

A list with components

<code>lambda</code>	vector of length 2 of selected smoothing parameters
<code>Yhat</code>	fitted data
<code>trace</code>	trace of the overall smoothing matrix
<code>gcv</code>	value of generalized cross validation
<code>Theta</code>	matrix of estimated coefficients

```

ff

*Construct a function-on-function regression term***Description**

Defines a term  $\int_{s_{lo,i}}^{s_{hi,i}} X_i(s)\beta(t,s)ds$  for inclusion in an `mgcv::gam`-formula (or `bam` or `gamm` or `gamm4::gamm4`) as constructed by `pffr`.

Defaults to a cubic tensor product B-spline with marginal first order differences penalties for  $\beta(t,s)$  and numerical integration over the entire range  $[s_{lo,i}, s_{hi,i}] = [\min(s_i), \max(s_i)]$  by using Simpson weights. Can't deal with any missing  $X(s)$ , unequal lengths of  $X_i(s)$  not (yet?) possible. Unequal integration ranges for different  $X_i(s)$  should work.  $X_i(s)$  is assumed to be numeric (duh...).

**Usage**

```
ff(X, yind = NULL, xind = seq(0, 1, l = ncol(X)), basistype = c("te",
  "t2", "ti", "s", "tes"), integration = c("simpson", "trapezoidal",
  "riemann"), L = NULL, limits = NULL, splinepars = if (basistype !=
  "s") { list(bs = "ps", m = list(c(2, 1), c(2, 1)), k = c(5, 5)) }
  else { list(bs = "tp", m = NA) }, check.ident = TRUE)
```

**Arguments**

<code>X</code>	an $n$ by <code>ncol(xind)</code> matrix of function evaluations $X_i(s_{i1}), \dots, X_i(s_{iS}); i = 1, \dots, n$ .
<code>yind</code>	<i>DEPRECATED</i> used to supply matrix (or vector) of indices of evaluations of $Y_i(t)$ , no longer used.
<code>xind</code>	vector of indices of evaluations of $X_i(s)$ , i.e. $(s_1, \dots, s_S)$
<code>basistype</code>	defaults to "te", i.e. a tensor product spline to represent $\beta(t,s)$ . Alternatively, use "s" for bivariate basis functions (see <code>mgcv</code> 's <code>s</code> ) or "t2" for an alternative parameterization of tensor product splines (see <code>mgcv</code> 's <code>t2</code> ).

integration	method used for numerical integration. Defaults to "simpson"'s rule for calculating entries in L. Alternatively and for non-equidistant grids, "trapezoidal" or "riemann". "riemann" integration is always used if limits is specified
L	optional: an n by ncol(xind) matrix giving the weights for the numerical integration over s.
limits	defaults to NULL for integration across the entire range of $X(s)$ , otherwise specifies the integration limits $s_{hi}(t), s_{lo}(t)$ : either one of "s<t" or "s<=t" for $(s_{hi}(t), s_{lo}(t)) = (t, 0]$ or $[t, 0]$ , respectively, or a function that takes s as the first and t as the second argument and returns TRUE for combinations of values (s, t) if s falls into the integration range for the given t. This is an experimental feature and not well tested yet; use at your own risk.
splinepars	optional arguments supplied to the basistype-term. Defaults to a cubic tensor product B-spline with marginal first difference penalties, i.e. <code>list(bs="ps", m=list(c(2,1),c(2,1)))</code> . See <a href="#">te</a> or <a href="#">s</a> in <b>mgcv</b> for details
check.ident	check identifiability of the model spec. See Details and References. Defaults to TRUE.

### Details

If `check.ident==TRUE` and `basistype!="s"` (the default), the routine checks conditions for non-identifiability of the effect. This occurs if a) the marginal basis for the functional covariate is rank-deficient (typically because the functional covariate has lower rank than the spline basis along its index) and simultaneously b) the kernel of  $\text{Cov}(X(s))$  is not disjoint from the kernel of the marginal penalty over s. In practice, a) occurs quite frequently, and b) occurs usually because curve-wise mean centering has removed all constant components from the functional covariate.

If there is kernel overlap,  $\beta(t, s)$  is constrained to be orthogonal to functions in that overlap space (e.g., if the overlap contains constant functions, constraints " $\int \beta(t, s) ds = 0$  for all t" are enforced). See reference for details.

A warning is always given if the effective rank of  $\text{Cov}(X(s))$  (defined as the number of eigenvalues accounting for at least 0.995 of the total variance in  $X_i(s)$ ) is lower than 4. If  $X_i(s)$  is of very low rank, `ffpc`-term may be preferable.

### Value

A list containing

call	a "call" to <a href="#">te</a> (or <a href="#">s</a> or <a href="#">t2</a> ) using the appropriately constructed covariate and weight matrices
data	a list containing the necessary covariate and weight matrices

### See Also

mgcv's [linear.functional.terms](#)

---

 ffpc

---

*Construct a PC-based function-on-function regression term*

---

### Description

Defines a term  $\int X_i(s)\beta(t, s)ds$  for inclusion in an mgcv::gam-formula (or bam or gamm or gamm4:::gamm4) as constructed by [pffr](#).

### Usage

```
ffpc(X, yind = NULL, xind = seq(0, 1, length = ncol(X)),
      splinepars = list(bs = "ps", m = c(2, 1), k = 8),
      decomppars = list(pve = 0.99, useSymm = TRUE), npc.max = 15)
```

### Arguments

X	an n by ncol(xind) matrix of function evaluations $X_i(s_{i1}), \dots, X_i(s_{iS}); i = 1, \dots, n$ .
yind	<i>DEPRECATED</i> used to supply matrix (or vector) of indices of evaluations of $Y_i(t)$ , no longer used.
xind	matrix (or vector) of indices of evaluations of $X_i(t)$ , defaults to <code>seq(0, 1, length=ncol(X))</code> .
splinepars	optional arguments supplied to the <code>basis</code> -term. Defaults to a cubic B-spline with first difference penalties and 8 basis functions for each $\tilde{\beta}_k(t)$ .
decomppars	parameters for the FPCA performed with <a href="#">fpca.sc</a> .
npc.max	maximal number $K$ of FPCs to use, regardless of <code>decomppars</code> ; defaults to 15

### Details

In contrast to [ff](#), `ffpc` does an FPCA decomposition  $X(s) \approx \sum_{k=1}^K \xi_{ik} \Phi_k(s)$  using [fpca.sc](#) and represents  $\beta(t, s)$  in the function space spanned by these  $\Phi_k(s)$ . That is, since

$$\int X_i(s)\beta(t, s)ds = \sum_{k=1}^K \xi_{ik} \int \Phi_k(s)\beta(s, t)ds = \sum_{k=1}^K \xi_{ik} \tilde{\beta}_k(t),$$

the function-on-function term can be represented as a sum of  $K$  univariate functions  $\tilde{\beta}_k(t)$  in  $t$  each multiplied by the FPC scores  $\xi_{ik}$ . The truncation parameter  $K$  is chosen as described in [fpca.sc](#). Using this instead of `ff()` can be beneficial if the covariance operator of the  $X_i(s)$  has low effective rank (i.e., if  $K$  is small). If the covariance operator of the  $X_i(s)$  is of (very) high rank, i.e., if  $K$  is large, `ffpc()` will not be very efficient.

To reduce model complexity, the  $\tilde{\beta}_k(t)$  all have a single joint smoothing parameter (in mgcv, they get the same id, see [s](#)).

Please see [pffr](#) for details on model specification and implementation.

### Value

A list containing the necessary information to construct a term to be included in a `mgcv::gam`-formula.

# fits are very similar:
all.equal(fitted(m.pc), fitted(m.ff))

# plot implied coefficient surfaces:
layout(t(1:3))
persp(t, s, t(beta.st), theta=50, phi=40, main="Truth",
  ticktype="detailed")
plot(m.ff, select=1, pers=TRUE, zlim=range(beta.st), theta=50, phi=40,
```

```

        ticktype="detailed")
title(main="ff()")
ffpcplot(m.pc, type="surf", auto.layout=FALSE, theta = 50, phi = 40)
title(main="ffpc()")

# show default ffpcplot:
ffpcplot(m.pc)

## End(Not run)

```

ffpcplot

*Plot PC-based function-on-function regression terms***Description**

Convenience function for graphical summaries of ffpc-terms from a pffr fit.

**Usage**

```

ffpcplot(object, type = c("fpc+surf", "surf", "fpc"), pages = 1,
  se.mult = 2, ticktype = "detailed", theta = 30, phi = 30,
  plot = TRUE, auto.layout = TRUE)

```

**Arguments**

object	a fitted pffr-model
type	one of "fpc+surf", "surf" or "fpc": "surf" shows a perspective plot of the coefficient surface implied by the estimated effect functions of the FPC scores, "fpc" shows three plots: 1) a scree-type plot of the estimated eigenvalues of the functional covariate, 2) the estimated eigenfunctions, and 3) the estimated coefficient functions associated with the FPC scores. Defaults to showing both.
pages	the number of pages over which to spread the output. Defaults to 1. (Irrelevant if auto.layout=FALSE.)
se.mult	display estimated coefficient functions associated with the FPC scores with plus/minus this number time the estimated standard error. Defaults to 2.
ticktype	see <a href="#">persp</a> .
theta	see <a href="#">persp</a> .
phi	see <a href="#">persp</a> .
plot	produce plots or only return plotting data? Defaults to TRUE.
auto.layout	should the the function set a suitable layout automatically? Defaults to TRUE

**Value**

primarily produces plots, invisibly returns a list containing the data used for the plots.

Fabian Scheipl

**Examples**

```
## Not run:
#see ?ffpc

## End(Not run)
```

fgam

*Functional Generalized Additive Models***Description**

Implements functional generalized additive models for functional and scalar covariates and scalar responses. Additionally implements functional linear models. This function is a wrapper for `mgcv`'s `gam` and its siblings to fit models of the general form

$$g(E(Y_i)) = \beta_0 + \int_{T_1} F(X_{i1}, t) dt + \int_{T_2} \beta(t) X_{i2} dt + f(z_{i1}) + f(z_{i2}, z_{i3}) + \dots$$

with a scalar (but not necessarily continuous) response  $Y$ , and link function  $g$

**Usage**

```
fgam(formula, fitter = NA, tensortype = c("te", "t2"), ...)
```

**Arguments**

formula	a formula with special terms as for <code>gam</code> , with additional special terms <code>af()</code> , <code>lf()</code> , <code>re()</code> .
fitter	the name of the function used to estimate the model. Defaults to <code>gam</code> if the matrix of functional responses has less than $2e5$ data points and to <code>bam</code> if not. "gamm" (see <code>gamm</code> ) and "gamm4" (see <code>gamm4</code> ) are valid options as well.
tensortype	defaults to <code>te</code> , other valid option is <code>t2</code>
...	additional arguments that are valid for <code>gam</code> or <code>bam</code> ; for example, specify a <code>gamma &gt; 1</code> to increase amount of smoothing when using GCV to choose smoothing parameters or <code>method="REML"</code> to change to REML for estimation of smoothing parameters (default is GCV).

**Value**

a fitted `fgam`-object, which is a `gam`-object with some additional information in a `fgam`-entry. If `fitter` is "gamm" or "gamm4", only the `$gam` part of the returned list is modified in this way.

**Warning**

Binomial responses should be specified as a numeric vector rather than as a matrix or a factor.

```

---

 fosr

*Function-on-scalar regression*

---

## Description

Fit linear regression with functional responses and scalar predictors, with efficient selection of optimal smoothing parameters.

## Usage

```

fosr(formula = NULL, Y = NULL, fdoobj = NULL, data = NULL, X,
     con = NULL, argvals = NULL, method = c("OLS", "GLS", "mix"),
     gam.method = c("REML", "ML", "GCV.Cp", "GACV.Cp", "P-REML", "P-ML"),
     cov.method = c("naive", "mod.chol"), lambda = NULL, nbasis = 15,
     norder = 4, pen.order = 2, multi.sp = ifelse(method == "OLS",
     FALSE, TRUE), pve = 0.99, max.iter = 1, maxlam = NULL,
     cv1 = FALSE, scale = FALSE)

```

## Arguments

`formula`            Formula for fitting fosr. If used, `data` argument must not be null.

<code>Y, fobj</code>	the functional responses, given as either an $n \times d$ matrix <code>Y</code> or a functional data object (class " <code>fd</code> ") as in the <code>fd</code> package.
<code>data</code>	data frame containing the predictors and responses.
<code>X</code>	the model matrix, whose columns represent scalar predictors. Should ordinarily include a column of 1s.
<code>con</code>	a row vector or matrix of linear contrasts of the coefficient functions, to be constrained to equal zero.
<code>argvals</code>	the $d$ argument values at which the coefficient functions will be evaluated.
<code>method</code>	estimation method: "OLS" for penalized ordinary least squares, "GLS" for penalized generalized least squares, "mix" for mixed effect models.
<code>gam.method</code>	smoothing parameter selection method, to be passed to <code>gam</code> : "REML" for restricted maximum likelihood, "GCV.Cp" for generalized cross-validation.
<code>cov.method</code>	covariance estimation method: the current options are naive or modified Cholesky. See Details.
<code>lambda</code>	smoothing parameter value. If NULL, the smoothing parameter(s) will be estimated. See Details.
<code>nbasis, norder</code>	number of basis functions, and order of splines (the default, 4, gives cubic splines), for the B-spline basis used to represent the coefficient functions. When the functional responses are supplied using <code>fobj</code> , these arguments are ignored in favor of the values pertaining to the supplied object.
<code>pen.order</code>	order of derivative penalty.
<code>multi.sp</code>	a logical value indicating whether separate smoothing parameters should be estimated for each coefficient function. Currently must be FALSE if <code>method = "OLS"</code> .
<code>pve</code>	if <code>method = 'mix'</code> , the percentage of variance explained by the principal components; defaults to 0.99.
<code>max.iter</code>	maximum number of iterations if <code>method = "GLS"</code> .
<code>maxlam</code>	maximum smoothing parameter value to consider (when <code>lamvec=NULL</code> ; see <code>lofocv</code> ).
<code>cv1</code>	logical value indicating whether a cross-validation score should be computed even if a single fixed <code>lambda</code> is specified (when <code>method = "OLS"</code> ).
<code>scale</code>	logical value or vector determining scaling of the matrix <code>X</code> (see <code>scale</code> , to which the value of this argument is passed).

## Details

The GLS method requires estimating the residual covariance matrix, which has dimension  $d \times d$  when the responses are given by `Y`, or  $nbasis \times nbasis$  when they are given by `fobj`. When `cov.method = "naive"`, the ordinary sample covariance is used. But this will be singular, or non-singular but unstable, in high-dimensional settings, which are typical. `cov.method = "mod.chol"` implements the modified Cholesky method of Pourahmadi (1999) for estimation of covariance matrices whose inverse is banded. The number of bands is chosen to maximize the p-value for a sphericity test (Ledoit and Wolf, 2002) applied to the "prewhitened" residuals. Note, however, that the banded inverse covariance assumption is sometimes inappropriate, e.g., for periodic functional responses.

There are three types of values for argument `lambda`:

1. if NULL, the smoothing parameter is estimated by `gam` (package `mgcv`) if `method = "GLS"`, or by `optimize` if `method = "OLS"`;
2. if a scalar, this value is used as the smoothing parameter (but only for the initial model, if `method = "GLS"`);
3. if a vector, this is used as a grid of values for optimizing the cross-validation score (provided `method = "OLS"`; otherwise an error message is issued).

Please note that currently, if `multi.sp = TRUE`, then `lambda` must be NULL and `method` must be "GLS".

### Value

An object of class `fosr`, which is a list with the following elements:

<code>fd</code>	object of class "fd" representing the estimated coefficient functions. Its main components are a basis and a matrix of coefficients with respect to that basis.
<code>pca.resid</code>	if <code>method = "mix"</code> , an object representing a functional PCA of the residuals, performed by <code>fpca.sc</code> if the responses are in raw form or by <code>pca.fd</code> if in functional-data-object form.
<code>U</code>	if <code>method = "mix"</code> , an $n \times m$ matrix of random effects, where $m$ is the number of functional PC's needed to explain proportion <code>pve</code> of the residual variance. These random effects can be interpreted as shrunken FPC scores.
<code>yhat, resid</code>	objects of the same form as the functional responses (see arguments <code>Y</code> and <code>fdobj</code> ), giving the fitted values and residuals.
<code>est.func</code>	matrix of values of the coefficient function estimates at the points given by <code>argvals</code> .
<code>se.func</code>	matrix of values of the standard error estimates for the coefficient functions, at the points given by <code>argvals</code> .
<code>argvals</code>	points at which the coefficient functions are evaluated.
<code>fit</code>	fit object outputted by <code>amc</code> .
<code>edf</code>	effective degrees of freedom of the fit.
<code>lambda</code>	smoothing parameter, or vector of smoothing parameters.
<code>cv</code>	cross-validated integrated squared error if <code>method="OLS"</code> , otherwise NULL.
<code>roughness</code>	value of the roughness penalty.
<code>resp.type</code>	"raw" or "fd", indicating whether the responses were supplied in raw or functional-data-object form.

---

 fosr.perm

 Permutation testing for function-on-scalar regression
 

---

## Description

fosr.perm() is a wrapper function calling fosr.perm.fit(), which fits models to permuted data, followed by fosr.perm.test(), which performs the actual simultaneous hypothesis test. Calling the latter two functions separately may be useful for performing tests at different significance levels. By default, fosr.perm() produces a plot using the plot function for class fosr.perm.

## Usage

```
fosr.perm(Y = NULL, fdoj = NULL, X, con = NULL, X0 = NULL,
  con0 = NULL, argvals = NULL, lambda = NULL, lambda0 = NULL,
  multi.sp = FALSE, nperm, level = 0.05, plot = TRUE, xlabel = "",
  title = NULL, prelim = if (multi.sp) 0 else 15, ...)
```

```
fosr.perm.fit(Y = NULL, fdoj = NULL, X, con = NULL, X0 = NULL,
  con0 = NULL, argvals = NULL, lambda = NULL, lambda0 = NULL,
  multi.sp = FALSE, nperm, prelim, ...)
```

```
fosr.perm.test(x, level = 0.05)
```

```
## S3 method for class 'fosr.perm'
plot(x, level = 0.05, xlabel = "", title = NULL,
  ...)
```

## Arguments

Y, fdoj	the functional responses, given as either an $n \times d$ matrix Y or a functional data object (class "fd") as in the <b>fd</b> package.
X	the design matrix, whose columns represent scalar predictors.
con	a row vector or matrix of linear contrasts of the coefficient functions, to be restricted to equal zero.
X0	design matrix for the null-hypothesis model. If NULL, the null hypothesis is the intercept-only model.
con0	linear constraints for the null-hypothesis model.
argvals	the $d$ argument values at which the coefficient functions will be evaluated.
lambda	smoothing parameter value. If NULL, the smoothing parameter(s) will be estimated. See <a href="#">fosr</a> for details.
lambda0	smoothing parameter for null-hypothesis model.
multi.sp	a logical value indicating whether separate smoothing parameters should be estimated for each coefficient function. Currently must be FALSE if method = "OLS".

nperm	number of permutations.
level	significance level for the simultaneous test.
plot	logical value indicating whether to plot the real- and permuted-data pointwise F-type statistics.
xlabel	x-axis label for plots.
title	title for plot.
prelim	number of preliminary permutations. The smoothing parameter in the main permutations will be fixed to the median value from these preliminary permutations. If <code>prelim=0</code> , this is not done. Preliminary permutations are not available when <code>multi.sp = TRUE</code> (hence the complicated default).
...	for <code>fossr.perm</code> and <code>fossr.perm.fit</code> , additional arguments passed to <code>fossr</code> . These arguments may include <code>max.iter</code> , <code>method</code> , <code>gam.method</code> , and <code>scale</code> . For <code>plot.fossr.perm</code> , graphical parameters (see <a href="#">par</a> ) for the plot.
x	object of class <code>fossr.perm</code> , outputted by <code>fossr.perm</code> , <code>fossr.perm.fit</code> , or <code>fossr.perm.test</code> .

### Value

`fossr.perm` or `fossr.perm.test` produces an object of class `fossr.perm`, which is a list with the elements below. `fossr.perm.fit` also outputs an object of this class, but without the last five elements.

F	pointwise F-type statistics at each of the points given by <code>argvals</code> .
F.perm	a matrix, each of whose rows gives the pointwise F-type statistics for a permuted data set.
argvals	points at which F-type statistics are computed.
lambda.real	smoothing parameter(s) for the real-data fit.
lambda.prelim	smoothing parameter(s) for preliminary permuted-data fits.
lambda.perm	smoothing parameter(s) for main permuted-data fits.
lambda0.real, lambda0.prelim, lambda0.perm	as above, but for null hypothesis models.
level	significance level of the test.
critval	critical value for the test.
signif	vector of logical values indicating whether significance is attained at each of the points <code>argvals</code> .
n2s	subset of $1, \dots, \text{length}(\text{argvals})$ identifying the points at which the test statistic changes from non-significant to significant.
s2n	points at which the test statistic changes from significant to non-significant.

*Function-on Scalar Regression with variable selection*

---

**Description**

Implements an iterative algorithm for function-on-scalar regression with variable selection by alternatively updating the coefficients and covariance structure.

**Usage**

```
fosr.vs(formula, data, nbasis = 10, method = c("ls", "grLasso",
      "grMCP", "grSCAD"), epsilon = 1e-05, max.iter_num = 100)
```

**Arguments**

formula	an object of class " <a href="#">formula</a> ": an expression of the model to be fitted.
data	a data frame that contains the variables in the model.
nbasis	number of B-spline basis functions used.

method	group variable selection method to be used ("grLasso", "grMCP", "grSCAD" refer to group Lasso, group MCP and group SCAD, respectively) or "ls" for least squares estimation.
epsilon	the convergence criterion.
max.iter_num	maximum number of iterations.

### Value

A fitted fcsr.vs-object, which is a list with the following elements:

formula	an object of class " <a href="#">formula</a> ": an expression of the model to be fitted.
coefficients	the estimated coefficient functions.
fitted.values	the fitted curves.
residuals	the residual curves.
vcov	the estimated variance-covariance matrix when convergence is achieved.
method	group variable selection method to be used or "ls" for least squares estimation.

## End(Not run)

```

---

 fosr2s

*Two-step function-on-scalar regression*

---

### Description

This function performs linear regression with functional responses and scalar predictors by (1) fitting a separate linear model at each point along the function, and then (2) smoothing the resulting coefficients to obtain coefficient functions.

### Usage

```

fosr2s(Y, X, argvals = seq(0, 1, , ncol(Y)), nbasis = 15, norder = 4,
       pen.order = norder - 2, basistype = "bspline")

```

### Arguments

Y	the functional responses, given as an $n \times d$ matrix.
X	$n \times p$ model matrix, whose columns represent scalar predictors. Should ordinarily include a column of 1s.
argvals	the $d$ argument values at which the functional responses are evaluated, and at which the coefficient functions will be evaluated.
nbasis	number of basis functions used to represent the coefficient functions.
norder	norder of the spline basis, when basistype="bspline" (the default, 4, gives cubic splines).

pen.order	order of derivative penalty.
basistype	type of basis used. The basis is created by an appropriate constructor function from the <b>fd</b> package; see <a href="#">basisfd</a> . Only "bspline" and "fourier" are supported.

### Details

Unlike [foser](#) and [pffr](#), which obtain smooth coefficient functions by minimizing a penalized criterion, this function introduces smoothing only as a second step. The idea was proposed by Fan and Zhang (2000), who employed local polynomials rather than roughness penalization for the smoothing step.

### Value

An object of class `foser`, which is a list with the following elements:

fd	object of class " <b>fd</b> " representing the estimated coefficient functions. Its main components are a basis and a matrix of coefficients with respect to that basis.
raw.coef	$d \times p$ matrix of coefficient estimates from regressing on $X$ separately at each point along the function.
raw.se	$d \times p$ matrix of standard errors of the raw coefficient estimates.
yhat	$n \times d$ matrix of fitted values.
est.func	$d \times p$ matrix of coefficient function estimates, obtained by smoothing the columns of <code>raw.coef</code> .
se.func	$d \times p$ matrix of coefficient function standard errors.
argvals	points at which the coefficient functions are evaluated.
lambda	smoothing parameters (chosen by REML) used to smooth the $p$ coefficient functions with respect to the supplied basis.

```

---

fpc

*Construct a FPC regression term*

---

## Description

Constructs a functional principal component regression (Reiss and Ogden, 2007, 2010) term for inclusion in an mgcv: :gam-formula (or `bam` or `gamm` or `gamm4:::gamm`) as constructed by `pfr`. Currently only one-dimensional functions are allowed.

## Usage

```
fpc(X, argvals = NULL, method = c("svd", "fpca.sc", "fpca.face",
  "fpca.ssvd"), ncomp = NULL, pve = 0.99, penalize = (method ==
  "svd"), bs = "ps", k = 40, ...)
```

## Arguments

<code>X</code>	functional predictors, typically expressed as an $N$ by $J$ matrix, where $N$ is the number of columns and $J$ is the number of evaluation points. May include missing/sparse functions, which are indicated by NA values. Alternatively, can be an object of class "fd"; see <code>fd</code> .
<code>argvals</code>	indices of evaluation of $X$ , i.e. $(t_{i1}, \dots, t_{iJ})$ for subject $i$ . May be entered as either a length- $J$ vector, or as an $N$ by $J$ matrix. Indices may be unequally spaced. Entering as a matrix allows for different observations times for each subject. If NULL, defaults to an equally-spaced grid between 0 or 1 (or within <code>X\$basis\$rangeval</code> if $X$ is a fd object.)

method	the method used for finding principal components. The default is an unconstrained SVD of the $XB$ matrix. Alternatives include constrained (functional) principal components approaches
ncomp	number of principal components. if NULL, chosen by pve
pve	proportion of variance explained; used to choose the number of principal components
penalize	if TRUE, a roughness penalty is applied to the functional estimate. Defaults to TRUE if method=="svd" (corresponding to the FPCR_R method of Reiss and Ogden (2007)), and FALSE if method!="svd" (corresponding to FPCR_C).
bs	two letter character string indicating the mgcv-style basis to use for pre-smoothing $X$
k	the dimension of the pre-smoothing basis
...	additional options to be passed to <code>lf</code> . These include <code>argvals</code> , <code>integration</code> , and any additional options for the pre-smoothing basis (as constructed by <code>mgcv::s</code> ), such as <code>m</code> .

### Details

`fpc` is a wrapper for `lf`, which defines linear functional predictors for any type of basis for inclusion in a `pfr` formula. `fpc` simply calls `lf` with the appropriate options for the `fpc` basis and penalty construction.

This function implements both the FPCR-R and FPCR-C methods of Reiss and Ogden (2007). Both methods consist of the following steps:

1. project  $X$  onto a spline basis  $B$
2. perform a principal components decomposition of  $XB$
3. use those PC's as the basis in fitting a (generalized) functional linear model

This implementation provides options for each of these steps. The basis for in step 1 can be specified using the arguments `bs` and `k`, as well as other options via `...`; see `s` for these options. The type of PC-decomposition is specified with `method`. And the FLM can be fit either penalized or unpenalized via `penalize`.

The default is FPCR-R, which uses a b-spline basis, an unconstrained principal components decomposition using `svd`, and the FLM fit with a second-order difference penalty. FPCR-C can be selected by using a different option for `method`, indicating a constrained ("functional") PC decomposition, and by default an unpenalized fit of the FLM.

FPCR-R is also implemented in `fpcr`; here we implement the method for inclusion in a `pfr` formula.

### Value

The result of a call to `lf`.

### NOTE

Unlike `fpcr`, `fpc` within a `pfr` formula does not automatically decorrelate the functional predictors from additional scalar covariates.

---

fpca.face	<i>Functional principal component analysis with fast covariance estimation</i>
-----------	--

---

### Description

A fast implementation of the sandwich smoother (Xiao et al., 2013) for covariance matrix smoothing. Pooled generalized cross validation at the data level is used for selecting the smoothing parameter.

### Usage

```
fpca.face(Y = NULL, ydata = NULL, Y.pred = NULL, argvals = NULL,
  pve = 0.99, npc = NULL, var = FALSE, simul = FALSE,
  sim.alpha = 0.95, center = TRUE, knots = 35, p = 3, m = 2,
  lambda = NULL, alpha = 1, search.grid = TRUE,
  search.length = 100, method = "L-BFGS-B", lower = -20,
  upper = 20, control = NULL)
```

### Arguments

Y, ydata	the user must supply either Y, a matrix of functions observed on a regular grid, or a data frame ydata representing irregularly observed functions. See Details.
Y.pred	if desired, a matrix of functions to be approximated using the FPC decomposition.
argvals	numeric; function argument.
pve	proportion of variance explained: used to choose the number of principal components.
npc	how many smooth SVs to try to extract, if NA (the default) the hard thresholding rule of Gavish and Donoho (2014) is used (see Details, References).
var	logical; should an estimate of standard error be returned?
simul	logical; if TRUE curves will be simulated using Monte Carlo to obtain an estimate of the sim.alpha quantile at each argval; ignored if var == FALSE
sim.alpha	numeric; if simul==TRUE, quantile to estimate at each argval; ignored if var == FALSE
center	logical; center Y so that its column-means are 0? Defaults to TRUE
knots	number of knots to use or the vectors of knots; defaults to 35
p	integer; the degree of B-splines functions to use
m	integer; the order of difference penalty to use
lambda	smoothing parameter; if not specified smoothing parameter is chosen using <a href="#">optim</a> or a grid search
alpha	numeric; tuning parameter for GCV; see parameter gamma in <a href="#">gam</a>
search.grid	logical; should a grid search be used to find lambda? Otherwise, <a href="#">optim</a> is used

search.length	integer; length of grid to use for grid search for lambda; ignored if search.grid is FALSE
method	method to use; see <a href="#">optim</a>
lower	see <a href="#">optim</a>
upper	see <a href="#">optim</a>
control	see <a href="#">optim</a>

### Value

A list with components

1. `Yhat` - If `Y.pred` is specified, the smooth version of `Y.pred`. Otherwise, if `Y.pred=NULL`, the smooth version of `Y`.
2. `scores` - matrix of scores
3. `mu` - mean function
4. `npc` - number of principal components
5. `efunctions` - matrix of eigenvectors
6. `evalues` - vector of eigenvalues

if `var == TRUE` additional components are returned

1. `sigma2` - estimate of the error variance
2. `VarMats` - list of covariance function estimate for each subject
3. `diag.var` - matrix containing the diagonals of each matrix in
4. `crit.val` - list of estimated quantiles; only returned if `simul == TRUE`

}

```

## Description

Implements longitudinal functional data analysis (Park and Staicu, 2015). It decomposes longitudinally-observed functional observations in two steps. It first applies FPCA on a properly defined marginal covariance function and obtain estimated scores (mFPCA step). Then it further models the underlying process dynamics by applying another FPCA on a covariance of the estimated scores obtained in the mFPCA step. The function also allows to use a random effects model to study the underlying process dynamics instead of a KL expansion model in the second step. Scores in mFPCA step are estimated using numerical integration. Scores in sFPCA step are estimated under a mixed model framework.

## Usage

```
fpca.lfda(Y, subject.index, visit.index, obsT = NULL, funcArg = NULL,
  numTEvalPoints = 41, newdata = NULL, fbps.knots = c(5, 10),
  fbps.p = 3, fbps.m = 2, mFPCA.pve = 0.95, mFPCA.knots = 35,
  mFPCA.p = 3, mFPCA.m = 2, mFPCA.npc = NULL,
  LongiModel.method = c("fpca.sc", "lme"), sFPCA.pve = 0.95,
  sFPCA.nbasis = 10, sFPCA.npc = NULL, gam.method = "REML",
  gam.kT = 10)
```

## Arguments

Y	a matrix of which each row corresponds to one curve observed on a regular and dense grid (dimension of N by m; N = total number of observed functions; m = number of grid points)
subject.index	subject id; vector of length N with each element corresponding a row of Y
visit.index	index for visits (repeated measures); vector of length N with each element corresponding a row of Y
obsT	actual time of visits at which a function is observed; vector of length N with each element corresponding a row of Y
funcArg	numeric; function argument
numTEvalPoints	total number of evaluation time points for visits; used for pre-binning in sFPCA step; defaults to 41
newdata	an optional data frame providing predictors (i for subject id / Ltime for visit time) with which prediction is desired; defaults to NULL
fbps.knots	list of two vectors of knots or number of equidistant knots for all dimensions for a fast bivariate P-spline smoothing (fbps) method used to estimate a bivariate, smooth mean function; defaults to c(5,10); see fbps
fbps.p	integer; degrees of B-spline functions to use for a fbps method; defaults to 3; see fbps

fbps.m	integer; order of differencing penalty to use for a fbps method; defaults to 2; see fbps
mFPCA.pve	proportion of variance explained for a mFPCA step; used to choose the number of principal components (PCs); defaults to 0.95; see fpca.face
mFPCA.knots	number of knots to use or the vectors of knots in a mFPCA step; used for obtain a smooth estimate of a covariance function; defaults to 35; see fpca.face
mFPCA.p	integer; the degree of B-spline functions to use in a mFPCA step; defaults to 3; see fpca.face
mFPCA.m	integer; order of differencing penalty to use in a mFPCA step; defaults to 2; see fpca.face
mFPCA.npc	pre-specified value for the number of principal components; if given, it overrides pve; defaults to NULL; see fpca.face
LongiModel.method	model and estimation method for estimating covariance of estimated scores from a mFPCA step; either KL expansion model or random effects model; defaults to fpca.sc
sFPCA.pve	proportion of variance explained for sFPCA step; used to choose the number of principal components; defaults to 0.95; see fpca.sc
sFPCA.nbasis	number of B-spline basis functions used in sFPCA step for estimation of the mean function and bivariate smoothing of the covariance surface; defaults to 10; see fpca.sc
sFPCA.npc	pre-specified value for the number of principal components; if given, it overrides pve; defaults to NULL; see fpca.sc
gam.method	smoothing parameter estimation method when gam is used for predicting score functions at unobserved visit time, T; defaults to REML; see gam
gam.kT	dimension of basis functions to use; see gam

## Value

A list with components

obsData	observed data (input)
i	subject id
funcArg	function argument
visitTime	visit times
fitted.values	fitted values (in-sample); of the same dimension as Y
fitted.values.all	a list of which each component consists of a subject's fitted values at all pairs of evaluation points (s and T)
predicted.values	predicted values for variables provided in newdata
bivariateSmoothMeanFunc	estimated bivariate smooth mean function

mFPCA.efunctions estimated eigenfunction in a mFPCA step

mFPCA.evalues estimated eigenvalues in a mFPCA step

mFPCA.npc number of principal components selected with pre-specified pve in a mFPCA step

mFPCA.scree.eval estimated eigenvalues obtained with pre-specified pve = 0.9999; for scree plot

sFPCA.xiHat.bySubj a list of which each component consists of a subject's predicted score functions evaluated at equidistanced grid in direction of visit time, T

sFPCA.npc a vector of numbers of principal components selected in a sFPCA step with pre-specified pve; length of mFPCA.npc

mFPCA.covar estimated marginal covariance

sFPCA.longDynCov.k a list of estimated covariance of score function; length of mFPCA.npc

### Details

A random effects model is recommended when a set of visit times for all subjects and visits is not dense in its range.

---

fpca.sc

*Functional principal components analysis by smoothed covariance*

---

### Description

Decomposes functional observations using functional principal components analysis. A mixed model framework is used to estimate scores and obtain variance estimates.

### Usage

```

fpca.sc(Y = NULL, ydata = NULL, Y.pred = NULL, argvals = NULL,
        random.int = FALSE, nbasis = 10, pve = 0.99, npc = NULL,
        var = FALSE, simul = FALSE, sim.alpha = 0.95, useSymm = FALSE,
        makePD = FALSE, center = TRUE, cov.est.method = 2,
        integration = "trapezoidal")

```

### Arguments

Y, ydata	the user must supply either Y, a matrix of functions observed on a regular grid, or a data frame ydata representing irregularly observed functions. See Details.
Y.pred	if desired, a matrix of functions to be approximated using the FPC decomposition.
argvals	the argument values of the function evaluations in Y, defaults to a equidistant grid from 0 to 1.
random.int	If TRUE, the mean is estimated by <a href="#">gamm4</a> with random intercepts. If FALSE (the default), the mean is estimated by <a href="#">gam</a> treating all the data as independent.
nbasis	number of B-spline basis functions used for estimation of the mean function and bivariate smoothing of the covariance surface.
pve	proportion of variance explained: used to choose the number of principal components.
npc	prespecified value for the number of principal components (if given, this overrides pve).

var	TRUE or FALSE indicating whether model-based estimates for the variance of FPCA expansions should be computed.
simul	logical: should critical values be estimated for simultaneous confidence intervals?
sim.alpha	1 - coverage probability of the simultaneous intervals.
useSymm	logical, indicating whether to smooth only the upper triangular part of the naive covariance (when <code>cov.est.method==2</code> ). This can save computation time for large data sets, and allows for covariance surfaces that are very peaked on the diagonal.
makePD	logical: should positive definiteness be enforced for the covariance surface estimate?
center	logical: should an estimated mean function be subtracted from $Y$ ? Set to FALSE if you have already demeaned the data using your favorite mean function estimate.
cov.est.method	covariance estimation method. If set to 1, a one-step method that applies a bivariate smooth to the $y(s_1)y(s_2)$ values. This can be very slow. If set to 2 (the default), a two-step method that obtains a naive covariance estimate which is then smoothed.
integration	quadrature method for numerical integration; only 'trapezoidal' is currently supported.

## Details

This function computes a FPC decomposition for a set of observed curves, which may be sparsely observed and/or measured with error. A mixed model framework is used to estimate curve-specific scores and variances.

FPCA via kernel smoothing of the covariance function, with the diagonal treated separately, was proposed in Staniswalis and Lee (1998) and much extended by Yao et al. (2005), who introduced the 'PACE' method. `fpca.sc` uses penalized splines to smooth the covariance function, as developed by Di et al. (2009) and Goldsmith et al. (2013).

The functional data must be supplied as either

- an  $n \times d$  matrix  $Y$ , each row of which is one functional observation, with missing values allowed; or
- a data frame `ydata`, with columns `.id` (which curve the point belongs to, say  $i$ ), `.index` (function argument such as time point  $t$ ), and `.value` (observed function value  $Y_i(t)$ ).

## Value

An object of class `fpca` containing:

<code>Yhat</code>	FPC approximation (projection onto leading components) of $Y$ . <code>pred</code> if specified, or else of $Y$ .
<code>Y</code>	the observed data
<code>scores</code>	$n \times npc$ matrix of estimated FPC scores.
<code>mu</code>	estimated mean function (or a vector of zeroes if <code>center==FALSE</code> ).

efunctions	$d \times npc$ matrix of estimated eigenfunctions of the functional covariance, i.e., the FPC basis functions.
evalues	estimated eigenvalues of the covariance operator, i.e., variances of FPC scores.
npc	number of FPCs: either the supplied npc, or the minimum number of basis functions needed to explain proportion pve of the variance in the observed curves.
argvals	argument values of eigenfunction evaluations
sigma2	estimated measurement error variance.
diag.var	diagonal elements of the covariance matrices for each estimated curve.
VarMats	a list containing the estimated covariance matrices for each curve in $Y$ .
crit.val	estimated critical values for constructing simultaneous confidence intervals.

  )
)

Fit.MM = fpca.sc(ydata=ydata, var = TRUE, simul = FALSE)

## End(Not run)

```

## Description

Implements the algorithm of Huang, Shen, Buja (2008) for finding smooth right singular vectors of a matrix  $X$  containing (contaminated) evaluations of functional random variables on a regular, equidistant grid. If the number of smooth SVs to extract is not specified, the function hazards a guess for the appropriate number based on the asymptotically optimal truncation threshold under the assumption of a low rank matrix contaminated with i.i.d. Gaussian noise with unknown variance

derived in Donoho, Gavish (2013). Please note that Donoho, Gavish (2013) should be regarded as experimental for functional PCA, and will typically not work well if you have more observations than grid points.

### Usage

```
fpca.ssvd(Y = NULL, ydata = NULL, argvals = NULL, npc = NA,
  center = TRUE, maxiter = 15, tol = 1e-04, diffpen = 3,
  gridsearch = TRUE, alphagrid = 1.5^(-20:40), lower.alpha = 1e-05,
  upper.alpha = 1e+07, verbose = FALSE, integration = "trapezoidal")
```

### Arguments

Y	data matrix (rows: observations; columns: grid of eval. points)
ydata	a data frame ydata representing irregularly observed functions. NOT IMPLEMENTED for this method.
argvals	the argument values of the function evaluations in Y, defaults to a equidistant grid from 0 to 1. See Details.
npc	how many smooth SVs to try to extract, if NA (the default) the hard thresholding rule of Donoho, Gavish (2013) is used (see Details, References).
center	center Y so that its column-means are 0? Defaults to TRUE
maxiter	how many iterations of the power algorithm to perform at most (defaults to 15)
tol	convergence tolerance for power algorithm (defaults to 1e-4)
diffpen	difference penalty order controlling the desired smoothness of the right singular vectors, defaults to 3 (i.e., deviations from local quadratic polynomials).
gridsearch	use <a href="#">optimize</a> or a grid search to find GCV-optimal smoothing parameters? defaults to TRUE.
alphagrid	grid of smoothing parameter values for grid search
lower.alpha	lower limit for for smoothing parameter if !gridsearch
upper.alpha	upper limit for smoothing parameter if !gridsearch
verbose	generate graphical summary of progress and diagnostic messages? defaults to FALSE
integration	ignored, see Details.

### Details

Note that `fpca.ssvd` computes smoothed orthonormal eigenvectors of the supplied function evaluations (and associated scores), not (!) evaluations of the smoothed orthonormal eigenfunctions. The smoothed orthonormal eigenvectors are then rescaled by the length of the domain defined by `argvals` to have a quadratic integral approximately equal to one (instead of crossproduct equal to one), so they approximate the behavior of smooth eigenfunctions. If `argvals` is not equidistant, `fpca.ssvd` will simply return the smoothed eigenvectors without rescaling, with a warning.

**Value**

an `fzca` object like that returned from `fzca.sc`, with entries `Yhat`, the smoothed trajectories, `Y`, the observed data, scores, the estimated FPC loadings, `mu`, the column means of `Y` (or a vector of zeroes if `!center`), `efunctions`, the estimated smooth FPCs (note that these are orthonormal vectors, not evaluations of orthonormal functions if `argvals` is not equidistant), `evalues`, their associated eigenvalues, and `npc`, the number of smooth components that were extracted.

fpca2s

*Functional principal component analysis by a two-stage method***Description**

This function performs functional PCA by performing an ordinary singular value decomposition on the functional data matrix, then smoothing the right singular vectors by smoothing splines.

**Usage**

```

fpca2s(Y = NULL, ydata = NULL, argvals = NULL, npc = NA,
       center = TRUE, smooth = TRUE)

```

**Arguments**

Y	data matrix (rows: observations; columns: grid of eval. points)
ydata	a data frame ydata representing irregularly observed functions. NOT IMPLEMENTED for this method.
argvals	the argument values of the function evaluations in Y, defaults to a equidistant grid from 0 to 1. See Details.
npc	how many smooth SVs to try to extract, if NA (the default) the hard thresholding rule of Donoho, Gavish (2013) is used (see Details, References).
center	center Y so that its column-means are 0? Defaults to TRUE
smooth	logical; defaults to TRUE, if NULL, no smoothing of eigenvectors.

**Details**

Note that fpca2s computes smoothed orthonormal eigenvectors of the supplied function evaluations (and associated scores), not (!) evaluations of the smoothed orthonormal eigenfunctions. The smoothed orthonormal eigenvectors are then rescaled by the length of the domain defined by argvals to have a quadratic integral approximately equal to one (instead of crossproduct equal to one), so they approximate the behavior of smooth eigenfunctions. If argvals is not equidistant, fpca2s will simply return the smoothed eigenvectors without rescaling, with a warning.

**Value**

an fpca object like that returned from [fpca.sc](#), with entries Yhat, the smoothed trajectories, Y, the observed data, scores, the estimated FPC loadings, mu, the column means of Y (or a vector of zeroes if !center), efunctions, the estimated smooth FPCs (note that these are orthonormal vectors, not evaluations of orthonormal functions if argvals is not equidistant), evalues, their associated eigenvalues, and npc, the number of smooth components that were extracted.

**Usage**

```

fpcr(y, xfuncs = NULL, fdoj = NULL, ncomp = NULL, pve = 0.99,
     nbasis = NULL, basismat = NULL, penmat = NULL, argvals = NULL,
     covt = NULL, mean.signal.term = FALSE, spline.order = NULL,
     family = "gaussian", method = "REML", sp = NULL, pen.order = 2,
     cv1 = FALSE, nfold = 5, store.cv = FALSE, store.gam = TRUE, ...)

```

**Arguments**

<code>y</code>	scalar outcome vector.
<code>xfuncs</code>	for 1D predictors, an $n \times d$ matrix of signals/functional predictors, where $n$ is the length of <code>y</code> and $d$ is the number of sites at which each signal is defined. For 2D predictors, an $n \times d1 \times d2$ array representing $n$ images of dimension $d1 \times d2$ .
<code>fdoj</code>	functional data object (class "fd") giving the functional predictors. Allowed only for 1D functional predictors.
<code>ncomp</code>	number of principal components. If NULL, this is chosen by <code>pve</code> .
<code>pve</code>	proportion of variance explained: used to choose the number of principal components.
<code>nbasis</code>	number(s) of B-spline basis functions: either a scalar, or a vector of values to be compared. For 2D predictors, tensor product B-splines are used, with the given basis dimension(s) in each direction; alternatively, <code>nbasis</code> can be given in the form <code>list(v1,v2)</code> , in which case cross-validation will be performed for each

	combination of the first-dimension basis sizes in $v1$ and the second-dimension basis sizes in $v2$ . Ignored if <code>fdobj</code> is supplied. If <code>fdobj</code> is <i>not</i> supplied, this defaults to 40 (i.e., 40 B-spline basis functions) for 1D predictors, and 15 (i.e., tensor product B-splines with 15 functions per dimension) for 2D predictors.
<code>basismat</code>	a $d \times K$ matrix of values of $K$ basis functions at the $d$ sites.
<code>penmat</code>	a $K \times K$ matrix defining a penalty on the basis coefficients.
<code>argvals</code>	points at which the functional predictors and the coefficient function are evaluated. By default, if 1D functional predictors are given by the $n \times d$ matrix <code>xfuncs</code> , <code>argvals</code> is set to $d$ equally spaced points from 0 to 1; if they are given by <code>fdobj</code> , <code>argvals</code> is set to 401 equally spaced points spanning the domain of the given functions. For 2D (image) predictors supplied as an $n \times d1 \times d2$ array, <code>argvals</code> defaults to a list of (1) $d1$ equally spaced points from 0 to 1; (2) $d2$ equally spaced points from 0 to 1.
<code>covt</code>	covariates: an $n$ -row matrix, or a vector of length $n$ .
<code>mean.signal.term</code>	logical: should the mean of each subject's signal be included as a covariate?
<code>spline.order</code>	order of B-splines used, if <code>fdobj</code> is not supplied; defaults to 4, i.e., cubic B-splines.
<code>family</code>	generalized linear model family. Current version supports "gaussian" (the default) and "binomial".
<code>method</code>	smoothing parameter selection method, passed to function <code>gam</code> ; see the <code>gam</code> documentation for details.
<code>sp</code>	a fixed smoothing parameter; if NULL, an optimal value is chosen (see <code>method</code> ).
<code>pen.order</code>	order of derivative penalty applied when estimating the coefficient function; defaults to 2.
<code>cv1</code>	logical: should cross-validation be performed to select the best model if only one set of tuning parameters provided? By default, FALSE. Note that, if there are multiple sets of tuning parameters provided, <code>cv</code> is always performed.
<code>nfold</code>	the number of validation sets ("folds") into which the data are divided; by default, 5.
<code>store.cv</code>	logical: should a CV result table be in the output? By default, FALSE.
<code>store.gam</code>	logical: should the <code>gam</code> object be included in the output? Defaults to TRUE.
<code>...</code>	other arguments passed to function <code>gam</code> .

## Details

One-dimensional functional predictors can be given either in functional data object form, using argument `fdobj` (see the `fda` package of Ramsay, Hooker and Graves, 2009, and Method 1 in the example below), or explicitly, using `xfuncs` (see Method 2 in the example). In the latter case, arguments `basismat` and `penmat` can also be used to specify the basis and/or penalty matrices (see Method 3).

For two-dimensional predictors, functional data object form is not supported. Instead of radial B-splines as in Reiss and Ogden (2010), this implementation employs tensor product cubic B-splines, sometimes known as bivariate O-splines (Ormerod, 2008).

For purposes of interpreting the fitted coefficients, please note that the functional predictors are decorrelated from the scalar predictors before fitting the model (when there are no scalar predictors other than the intercept, this just means the columns of the functional predictor matrix are demeaned); see section 3.2 of Reiss (2006) for details.

### Value

A list with components

<code>gamObject</code>	if <code>store.gam = TRUE</code> , an object of class <code>gam</code> (see <code>gamObject</code> in the <code>mgecv</code> package documentation).
<code>fhat</code>	coefficient function estimate.
<code>se</code>	pointwise Bayesian standard error.
<code>undecor.coef</code>	undecorrelated coefficient for covariates.
<code>argvals</code>	the supplied value of <code>argvals</code> .
<code>cv.table</code>	a table giving the CV criterion for each combination of <code>nbasis</code> and <code>ncomp</code> , if <code>store.cv = TRUE</code> ; otherwise, the CV criterion only for the optimized combination of these parameters. Set to <code>NULL</code> if CV is not performed.
<code>nbasis, ncomp</code>	when CV is performed, the values of <code>nbasis</code> and <code>comp</code> that minimize the CV criterion.

---

f_sum	<i>Sum computation 1</i>
-------	--------------------------

---

### Description

Internal function used compute a sum in FPCA-based covariance updates

### Usage

```
f_sum(mu.q.c, sig.q.c, theta, obspts.mat)
```

### Arguments

mu.q.c	current value of mu.q.c
sig.q.c	current value of sig.q.c
theta	spline basis
obspts.mat	matrix indicating the points on which data is observed

### Author(s)

Jeff Goldsmith <ajg2202@cumc.columbia.edu>

---

f_sum2	<i>Sum computation 2</i>
--------	--------------------------

---

### Description

Internal function used compute a sum in FPCA-based covariance updates

### Usage

```
f_sum2(y, fixef, mu.q.c, kt, theta)
```

### Arguments

y	outcome matrix
fixef	current estimate of fixed effects
mu.q.c	current value of mu.q.c
kt	number of basis functions
theta	spline basis

### Author(s)

Jeff Goldsmith <ajg2202@cumc.columbia.edu>

---

f_sum4	<i>Sum computation 2</i>
--------	--------------------------

---

**Description**

Internal function used compute a sum in FPCA-based covariance updates

**Usage**

```
f_sum4(mu.q.c, sig.q.c, mu.q.bpsi, sig.q.bpsi, theta, obspts.mat)
```

**Arguments**

mu.q.c	current value of mu.q.c
sig.q.c	current value of sig.q.c
mu.q.bpsi	current value of mu.q.bpsi
sig.q.bpsi	current value of sig.q.bpsi
theta	current value of theta
obspts.mat	matrix indicating where curves are observed

**Author(s)**

Jeff Goldsmith <ajg2202@cumc.columbia.edu>

---

f_trace	<i>Trace computation</i>
---------	--------------------------

---

**Description**

Internal function used compute a trace in FPCA-based covariance updates

**Usage**

```
f_trace(Theta_i, Sig_q_Bpsi, Kp, Kt)
```

**Arguments**

Theta_i	basis functions on observed grid points
Sig_q_Bpsi	variance of FPC basis coefficients
Kp	number of FPCs
Kt	number of spline basis functions

**Author(s)**

Jeff Goldsmith <ajg2202@cumc.columbia.edu>

gasoline

*Octane numbers and NIR spectra of gasoline***Description**

Near-infrared reflectance spectra and octane numbers of 60 gasoline samples. Each NIR spectrum consists of  $\log(1/\text{reflectance})$  measurements at 401 wavelengths, in 2-nm intervals from 900 nm to 1700 nm. We thank Prof. John Kalivas for making this data set available.

**Format**

A data frame comprising

**octane** a numeric vector of octane numbers for the 60 samples.

**NIR** a 60 x 401 matrix of NIR spectra.

**Source**

gibbs\_cs\_fPCA

*Cross-sectional FoSR using a Gibbs sampler and FPCA***Description**

Fitting function for function-on-scalar regression for cross-sectional data. This function estimates model parameters using a Gibbs sampler and estimates the residual covariance surface using FPCA.

**Usage**

```
gibbs_cs_fPCA(formula, Kt = 5, Kp = 2, data = NULL, verbose = TRUE,
  N.iter = 5000, N.burn = 1000, SEED = NULL, sig2.me = 0.01,
  alpha = 0.1, Aw = NULL, Bw = NULL, Apsi = NULL, Bpsi = NULL)
```

**Arguments**

formula	a formula indicating the structure of the proposed model.
Kt	number of spline basis functions used to estimate coefficient functions
Kp	number of FPCA basis functions to be estimated
data	an optional data frame, list or environment containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which the function is called.
verbose	logical defaulting to TRUE – should updates on progress be printed?
N.iter	number of iterations used in the Gibbs sampler
N.burn	number of iterations discarded as burn-in
SEED	seed value to start the sampler; ensures reproducibility
sig2.me	starting value for measurement error variance
alpha	tuning parameter balancing second-derivative penalty and zeroth-derivative penalty (alpha = 0 is all second-derivative penalty)
Aw	hyperparameter for inverse gamma controlling variance of spline terms for population-level effects
Bw	hyperparameter for inverse gamma controlling variance of spline terms for population-level effects
Apsi	hyperparameter for inverse gamma controlling variance of spline terms for FPC effects
Bpsi	hyperparameter for inverse gamma controlling variance of spline terms for FPC effects

gibbs\_cs\_wish

---

*Cross-sectional FoSR using a Gibbs sampler and Wishart prior*

---

**Description**

Fitting function for function-on-scalar regression for cross-sectional data. This function estimates model parameters using a Gibbs sampler and estimates the residual covariance surface using a Wishart prior.

**Usage**

```
gibbs_cs_wish(formula, Kt = 5, data = NULL, verbose = TRUE,  
  N.iter = 5000, N.burn = 1000, alpha = 0.1, min.iter = 10,  
  max.iter = 50, Aw = NULL, Bw = NULL, v = NULL, SEED = NULL)
```

**Arguments**

formula	a formula indicating the structure of the proposed model.
Kt	number of spline basis functions used to estimate coefficient functions
data	an optional data frame, list or environment containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which the function is called.
verbose	logical defaulting to TRUE – should updates on progress be printed?
N.iter	number of iterations used in the Gibbs sampler
N.burn	number of iterations discarded as burn-in
alpha	tuning parameter balancing second-derivative penalty and zeroth-derivative penalty (alpha = 0 is all second-derivative penalty)
min.iter	minimum number of iterations
max.iter	maximum number of iterations
Aw	hyperparameter for inverse gamma controlling variance of spline terms for population-level effects
Bw	hyperparameter for inverse gamma controlling variance of spline terms for population-level effects
v	hyperparameter for inverse Wishart prior on residual covariance
SEED	seed value to start the sampler; ensures reproducibility

---

gls\_cs

---

*Cross-sectional FoSR using GLS*

---

## Description

Fitting function for function-on-scalar regression for cross-sectional data. This function estimates model parameters using GLS: first, an OLS estimate of spline coefficients is estimated; second, the residual covariance is estimated using an FPC decomposition of the OLS residual curves; finally, a GLS estimate of spline coefficients is estimated. Although this is in the 'BayesFoSR' package, there is nothing Bayesian about this FoSR.

## Usage

```
gls_cs(formula, data = NULL, Kt = 5, basis = "bs", sigma = NULL,
        verbose = TRUE, CI.type = "pointwise")
```

## Arguments

formula	a formula indicating the structure of the proposed model.
data	an optional data frame, list or environment containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which the function is called.
Kt	number of spline basis functions used to estimate coefficient functions
basis	basis type; options are "bs" for b-splines and "pbs" for periodic b-splines
sigma	optional covariance matrix used in GLS; if NULL, OLS will be used to estimate fixed effects, and the covariance matrix will be estimated from the residuals.
verbose	logical defaulting to TRUE – should updates on progress be printed?
CI.type	Indicates CI type for coefficient functions; options are "pointwise" and "simultaneous"

lf

*Construct an FLM regression term***Description**

Defines a term  $\int_T \beta(t) X_i(t) dt$  for inclusion in an `mgcv::gam`-formula (or `bam` or `gamm` or `gamm4::gamm`) as constructed by `pfr`, where  $\beta(t)$  is an unknown coefficient function and  $X_i(t)$  is a functional predictor on the closed interval  $T$ . See `smooth.terms` for a list of basis and penalty options; the default is thin-plate regression splines, as this is the default option for `s`.

**Usage**

```
lf(X, argvals = NULL, xind = NULL, integration = c("simpson",
  "trapezoidal", "riemann"), L = NULL, presmooth = NULL,
  presmooth.opts = NULL, ...)
```

**Arguments**

<code>X</code>	functional predictors, typically expressed as an N by J matrix, where N is the number of columns and J is the number of evaluation points. May include missing/sparse functions, which are indicated by NA values. Alternatively, can be an object of class "fd"; see <code>fd</code> .
<code>argvals</code>	indices of evaluation of X, i.e. $(t_{i1}, \dots, t_{iJ})$ for subject $i$ . May be entered as either a length-J vector, or as an N by J matrix. Indices may be unequally spaced. Entering as a matrix allows for different observations times for each subject. If NULL, defaults to an equally-spaced grid between 0 or 1 (or within <code>X\$basis\$rangeval</code> if X is a fd object.)
<code>xind</code>	same as <code>argvals</code> . It will not be supported in the next version of <code>refund</code> .
<code>integration</code>	method used for numerical integration. Defaults to "simpson"'s rule for calculating entries in L. Alternatively and for non-equidistant grids, "trapezoidal" or "riemann".
<code>L</code>	an optional N by <code>ncol(argvals)</code> matrix giving the weights for the numerical integration over t. If present, overrides <code>integration</code> .
<code>presmooth</code>	string indicating the method to be used for preprocessing functional predictor prior to fitting. Options are <code>fpca.sc</code> , <code>fpca.face</code> , <code>fpca.ssvd</code> , <code>fpca.bspline</code> , and <code>fpca.interpolate</code> . Defaults to NULL indicating no preprocessing. See <code>create.prep.func</code> .
<code>presmooth.opts</code>	list including options passed to preprocessing method <code>create.prep.func</code> .
<code>...</code>	optional arguments for basis and penalization to be passed to <code>mgcv::s</code> . These could include, for example, "bs", "k", "m", etc. See <code>s</code> for details.

**Value**

a list with the following entries

call	a call to <code>te</code> (or <code>s</code> , <code>t2</code> ) using the appropriately constructed covariate and weight matrices
argvals	the <code>argvals</code> argument supplied to <code>lf</code>
L	the matrix of weights used for the integration
xindname	the name used for the functional predictor variable in the formula used by <code>mgcv</code>
tindname	the name used for <code>argvals</code> variable in the formula used by <code>mgcv</code>
LXname	the name used for the L variable in the formula used by <code>mgcv</code>
presmooth	the <code>presmooth</code> argument supplied to <code>lf</code>
prep.func	a function that preprocesses data based on the preprocessing method specified in <code>presmooth</code> . See <a href="#">create.prep.func</a>

```

lf.vd

*Construct a VDFR regression term***Description**

This function defines the a variable-domain functional regression term for inclusion in an `gam`-formula (or `bam` or `gamm` or `gamm4::gamm` as constructed by `pfr`. These are functional predictors for which each function is observed over a domain of different width. The default is the term  $1/T_i \int_0^{T_i} X_i(t)\beta(t, T_i)dt$ , where  $X_i(t)$  is a functional predictor of length  $T_i$  and  $\beta(t, T_i)$  is an unknown bivariate coefficient function. Various domain transformations are available, such as lagging or domain-standardizing the coordinates, or parameterizing the interactions; these often result in improved model fit. Basis choice is fully customizable using the options of `s` and `te`.

**Usage**

```
lf.vd(X, argvals = seq(0, 1, l = ncol(X)), vd = NULL,
      integration = c("simpson", "trapezoidal", "riemann"), L = NULL,
      basistype = c("s", "te", "t2"), transform = NULL, mp = TRUE, ...)
```

**Arguments**

<code>X</code>	matrix containing variable-domain functions. Should be $N \times J$ , where $N$ is the number of subjects and $J$ is the maximum number of time points per subject. Most rows will have NA values in the right-most columns, corresponding to unobserved time points.
<code>argvals</code>	indices of evaluation of <code>X</code> , i.e. $(t_{i1}, \dots, t_{iJ})$ for subject $i$ . May be entered as either a length- $J$ vector, or as an $N$ by $J$ matrix. Indices may be unequally spaced. Entering as a matrix allows for different observations times for each subject.
<code>vd</code>	vector of values of containing the variable-domain width ( $T_i$ above). Defaults to the <code>argvals</code> value corresponding to the last non-NA element of $X_i(t)$ .
<code>integration</code>	method used for numerical integration. Defaults to "simpson"'s rule for calculating entries in <code>L</code> . Alternatively and for non-equidistant grids, "trapezoidal" or "riemann".
<code>L</code>	an optional $N$ by $\text{ncol}(\text{argvals})$ matrix giving the weights for the numerical integration over <code>t</code> . If present, overrides <code>integration</code> .
<code>basistype</code>	character string indicating type of bivariate basis used. Options include "s" (the default), "te", and "t2", which correspond to <code>mgcv::s</code> , <code>mgcv::te</code> , and <code>mgcv::t2</code> .
<code>transform</code>	character string indicating an optional basis transformation; see Details for options.
<code>mp</code>	for <code>transform=="linear"</code> or <code>transform=="quadratic"</code> , TRUE to use multiple penalties for the smooth (one for each marginal basis). If FALSE, penalties are concatenated into a single block-diagonal penalty matrix (with one smoothing parameter).

... optional arguments for basis and penalization to be passed to the function indicated by `basistype`. These could include, for example, "bs", "k", "m", etc. See [te](#) or [s](#) for details.

## Details

The variable-domain functional regression model uses the term  $\frac{1}{T_i} \int_0^{T_i} X_i(t) \beta(t, T_i) dt$  to incorporate a functional predictor with subject-specific domain width. This term imposes a smooth (non-parametric) interaction between  $t$  and  $T_i$ . The domain of the coefficient function is the triangular (or trapezoidal) surface defined by  $t, T_i : 0 \leq t \leq T_i$ . The default basis uses bivariate thin-plate regression splines.

Different basis transformations can result in different properties; see Gellar, et al. (2014) for a more complete description. We make five basis transformations easily accessible using the `transform` argument. This argument is a character string that can take one of the following values:

1. "lagged": transforms `argvals` to `argvals - vd`
2. "standardized": transforms `argvals` to `argvals/vd`, and then rescales `vd` linearly so it ranges from 0 to 1
3. "linear": first transforms the domain as in "standardized", then parameterizes the interaction with "vd" to be linear
4. "quadratic": first transforms the domain as in "standardized", then parameterizes the interaction with "vd" to be quadratic
5. "noInteraction": first transforms the domain as in "standardized", then reduces the bivariate basis to univariate with no effect of `vd`. This would be equivalent to using [lf](#) on the domain-standardized predictor functions.

The practical effect of using the "lagged" basis is to increase smoothness along the right (diagonal) edge of the resultant estimate. The practical effect of using a "standardized" basis is to allow for greater smoothness at high values of  $T_i$  compared to lower values.

These basis transformations rely on the basis constructors available in the `mgcvTrans` package. For more specific control over the transformations, you can use `bs="dt"` and/or `bs="pi"`; see [smooth.construct.dt.smooth.spec](#) or [smooth.construct.pi.smooth.spec](#) for an explanation of the options (entered through the `xt` argument of `lf.vd/s`).

Note that tensor product bases are only recommended when a standardized transformation is used. Without this transformation, just under half of the "knots" used to define the basis will fall outside the range of the data and have no data available to estimate them. The penalty allows the corresponding coefficients to be estimated, but results may be unstable.

## Value

a list with the following entries

<code>call</code>	a call to <code>s</code> or <code>te</code> , using the appropriately constructed weight matrices
<code>data</code>	data used by the call, which includes the matrices indicated by <code>argname</code> , <code>Tindname</code> , and <code>LXname</code>
<code>L</code>	the matrix of weights used for the integration
<code>argname</code>	the name used for the <code>argvals</code> variable in the formula used by <code>mgcv::gam</code>

Tindname           the name used for the Tind variable in the formula used by `mgcv::gam`  
 LXname             the name of the by variable used by `s` or `te` in the formula for `mgcv::gam`

lf\_old

*Construct an FLM regression term***Description**

Defines a term  $\int_T \beta(t) X_i(t) dt$  for inclusion in an `gam`-formula (or `bam` or `gamm` or `gamm4`) as constructed by `fgam`, where  $\beta(t)$  is an unknown coefficient function and  $X_i(t)$  is a functional predictor on the closed interval  $T$ . Defaults to a cubic B-spline with second-order difference penalties for estimating  $\beta(t)$ . The functional predictor must be fully observed on a regular grid.

**Usage**

```

lf_old(X, argvals = seq(0, 1, l = ncol(X)), xind = NULL,
       integration = c("simpson", "trapezoidal", "riemann"), L = NULL,
       splinepars = list(bs = "ps", k = min(ceiling(n/4), 40), m = c(2, 2)),
       presmooth = TRUE)

```

**Arguments**

<code>X</code>	an $N$ by $J = \text{ncol}(\text{argvals})$ matrix of function evaluations $X_i(t_{i1}), \dots, X_i(t_{iJ}); i = 1, \dots, N$ .
<code>argvals</code>	matrix (or vector) of indices of evaluations of $X_i(t)$ ; i.e. a matrix with $i$ th row $(t_{i1}, \dots, t_{iJ})$
<code>xind</code>	same as <code>argvals</code> . It will not be supported in the next version of <code>refund</code> .
<code>integration</code>	method used for numerical integration. Defaults to "simpson"'s rule for calculating entries in <code>L</code> . Alternatively and for non-equidistant grids, "trapezoidal" or "riemann". "riemann" integration is always used if <code>L</code> is specified
<code>L</code>	an optional $N$ by $\text{ncol}(\text{argvals})$ matrix giving the weights for the numerical integration over <code>t</code>
<code>splinepars</code>	optional arguments specifying options for representing and penalizing the functional coefficient $\beta(t)$ . Defaults to a cubic B-spline with second-order difference penalties, i.e. <code>list(bs="ps", m=c(2, 1))</code> See <code>te</code> or <code>s</code> for details
<code>presmooth</code>	logical; if true, the functional predictor is pre-smoothed prior to fitting. See <code>smooth.basisPar</code>

**Value**

a list with the following entries

1. `call` - a call to `te` (or `s`, `t2`) using the appropriately constructed covariate and weight matrices
2. `argvals` - the `argvals` argument supplied to `lf`
3. `L` - the matrix of weights used for the integration
4. `xindname` - the name used for the functional predictor variable in the formula used by `mgcv`
5. `tindname` - the name used for `argvals` variable in the formula used by `mgcv`
6. `LXname` - the name used for the `L` variable in the formula used by `mgcv`
7. `presmooth` - the `presmooth` argument supplied to `lf`
8. `Xfd` - an `fd` object from presmoothing the functional predictors using `smooth.basisPar`. Only present if `presmooth=TRUE`. See `fd`

lpeer

*Longitudinal Functional Models with Structured Penalties*

---

**Description**

Implements longitudinal functional model with structured penalties (Kundu et al., 2012) with scalar outcome, single functional predictor, one or more scalar covariates and subject-specific random intercepts through mixed model equivalence.

**Usage**

```
lpeer(Y, subj, t, funcs, argvals = NULL, covariates = NULL,
      comm.pen = TRUE, pentype = "Ridge", L.user = NULL, f_t = NULL,
      Q = NULL, phia = 10^3, se = FALSE, ...)
```

**Arguments**

<code>Y</code>	vector of all outcomes over all visits or timepoints
<code>subj</code>	vector containing the subject number for each observation
<code>t</code>	vector containing the time information when the observation are taken
<code>funcs</code>	matrix containing observed functional predictors as rows. Rows with NA and Inf values will be deleted.

argvals	matrix (or vector) of indices of evaluations of $X_i(t)$ ; i.e. a matrix with $i$ th row $(t_{i1}, \dots, t_{iJ})$
covariates	matrix of scalar covariates.
comm.pen	logical value indicating whether common penalty for all the components of regression function. Default is TRUE.
pen type	type of penalty: either decomposition based penalty ('DECOMP') or ridge ('RIDGE') or second-order difference penalty ('D2') or any user defined penalty ('USER'). For decomposition based penalty user need to specify Q matrix in Q argument (see details). For user defined penalty user need to specify L matrix in L argument (see details). For Ridge and second-order difference penalty, specification for arguments L and Q will be ignored. Default is 'RIDGE'.
L.user	penalty matrix. Need to be specified with pen type='USER'. When comm.pen=TRUE, Number of columns need to be equal with number of columns of matrix specified to funcs. When comm.pen=FALSE, Number of columns need to be equal with the number of columns of matrix specified to funcs times the number of components of regression function. Each row represents a constraint on functional predictor. This argument will be ignored when value of pen type is other than 'USER'.
f_t	vector or matrix with number of rows equal to number of total observations and number of columns equal to d (see details). If matrix then each column pertains to single function of time and the value in the column represents the realization corresponding to time vector t. The column with intercept or multiple of intercept will be dropped. A NULL value refers to time-invariant regression function. Default value is NULL.
Q	Q matrix to derive decomposition based penalty. Need to be specified with pen type='DECOMP'. When comm.pen=TRUE, number of columns must equal number of columns of matrix specified to funcs. When comm.pen=FALSE, Number of columns need to be equal with the number of columns of matrix specified to funcs times the number of components of regression function. Each row represents a basis function where functional predictor is expected lie according to prior belief. This argument will be ignored when value of pen type is other than 'DECOMP'.
phia	scalar value of a in decomposition based penalty. Needs to be specified with pen type='DECOMP'.
se	logical; calculate standard error when TRUE.
...	additional arguments passed to <a href="#">lme</a> .

## Details

If there are any missing or infinite values in Y, subj, t, covariates, funcs and f\_t, the corresponding row (or observation) will be dropped, and infinite values are not allowed for these arguments. Neither Q nor L may contain missing or infinite values. `lpeer()` fits the following model:

$$y_{i(t)} = X_{i(t)}^T \beta + \int W_{i(t)}(s) \gamma(t, s) ds + Z_{i(t)} u_i + \epsilon_{i(t)}$$

where  $\epsilon_{i(t)} \sim N(0, \sigma^2)$  and  $u_i \sim N(0, \sigma_u^2)$ . For all the observations, predictor function  $W_{i(t)}(s)$  is evaluated at K sampling points. Here, regression function  $\gamma(t, s)$  is represented in terms of (d+1) component functions  $\gamma_0(s), \dots, \gamma_d(s)$  as follows

$$\gamma(t, s) = \gamma_0(s) + f_1(t)\gamma_1(s) + f_d(t)\gamma_d(s)$$

Values of  $y_{i(t)}$ ,  $X_{i(t)}$  and  $W_{i(t)}(s)$  are passed through argument `Y`, `covariates` and `funcs`, respectively. Number of elements or rows in `Y`, `t`, `subj`, `covariates` (if not `NULL`) and `funcs` need to be equal.

Values of  $f_1(t), \dots, f_d(t)$  are passed through `f_t` argument. The matrix passed through `f_t` argument should have `d` columns where each column represents one and only one of  $f_1(t), \dots, f_d(t)$ .

The estimate of  $(d+1)$  component functions  $\gamma_0(s), \dots, \gamma_d(s)$  is obtained as penalized estimated. The following 3 types of penalties can be used for a component function:

i. Ridge:  $I_K$

ii. Second-order difference:  $[d_{i,j}]$  with  $d_{i,i} = d_{i,i+2} = 1, d_{i,i+1} = -2$ , otherwise  $d_{i,j} = 0$

iii. Decomposition based penalty:  $bP_Q + a(I - P_Q)$  where  $P_Q = Q^T(QQ^T)^{-1}Q$

For Decomposition based penalty the user must specify `penType= 'DECOMP'` and the associated `Q` matrix must be passed through the `Q` argument. Alternatively, one can directly specify the penalty matrix by setting `penType= 'USER'` and using the `L` argument to supply the associated `L` matrix.

If `Q` (or `L`) matrix is similar for all the component functions then argument `comm.pen` should have value `TRUE` and in that case specified matrix to argument `Q` (or `L`) should have `K` columns. When `Q` (or `L`) matrix is different for all the component functions then argument `comm.pen` should have value `FALSE` and in that case specified matrix to argument `Q` (or `L`) should have `K(d+1)` columns. Here first `K` columns pertains to first component function, second `K` columns pertains to second component functions, and so on.

Default penalty is Ridge penalty for all the component functions and user needs to specify `'RIDGE'`. For second-order difference penalty, user needs to specify `'D2'`. When `penType` is `'RIDGE'` or `'D2'` the value of `comm.pen` is always `TRUE` and `comm.pen=FALSE` will be ignored.

## Value

A list containing:

<code>fit</code>	result of the call to <code>lme</code>
<code>fitted.vals</code>	predicted outcomes
<code>BetaHat</code>	parameter estimates for scalar covariates including intercept
<code>se.Beta</code>	standard error of parameter estimates for scalar covariates including intercept
<code>Beta</code>	parameter estimates with standard error for scalar covariates including intercept
<code>GammaHat</code>	estimates of components of regression functions. Each column represents one component function.
<code>Se.Gamma</code>	standard error associated with <code>GammaHat</code>
<code>AIC</code>	AIC value of fit (smaller is better)
<code>BIC</code>	BIC value of fit (smaller is better)
<code>logLik</code>	(restricted) log-likelihood at convergence
<code>lambda</code>	list of estimated smoothing parameters associated with each component function
<code>V</code>	conditional variance of <code>Y</code> treating only random intercept as random one.
<code>V1</code>	unconditional variance of <code>Y</code>

N	number of subjects
K	number of Sampling points in functional predictor
TotalObs	total number of observations over all subjects
Sigma.u	estimated sd of random intercept.
sigma	estimated within-group error standard deviation.

---

lpfr *Longitudinal penalized functional regression*

---

### Description

Implements longitudinal penalized functional regression (Goldsmith et al., 2012) for generalized linear functional models with scalar outcomes and subject-specific random intercepts.

### Usage

```
lpfr(Y, subj, covariates = NULL, funcs, kz = 30, kb = 30,
      smooth.cov = FALSE, family = "gaussian", method = "REML", ...)
```

### Arguments

Y	vector of all outcomes over all visits
subj	vector containing the subject number for each observation
covariates	matrix of scalar covariates
funcs	matrix or list of matrices containing observed functional predictors as rows. NA values are allowed.
kz	dimension of principal components basis for the observed functional predictors
kb	dimension of the truncated power series spline basis for the coefficient function
smooth.cov	logical; do you wish to smooth the covariance matrix of observed functions? Increases computation time, but results in smooth principal components
family	generalized linear model family
method	method for estimating the smoothing parameters; defaults to REML
...	additional arguments passed to <a href="#">gam</a> to fit the regression model.

### Details

Functional predictors are entered as a matrix or, in the case of multiple functional predictors, as a list of matrices using the `funcs` argument. Missing values are allowed in the functional predictors, but it is assumed that they are observed over the same grid. Functional coefficients and confidence bounds are returned as lists in the same order as provided in the `funcs` argument, as are principal component and spline bases.

### Value

fit	result of the call to <code>gam</code>
fitted.vals	predicted outcomes
betaHat	list of estimated coefficient functions
beta.covariates	parameter estimates for scalar covariates
ranef	vector of subject-specific random intercepts

X	design matrix used in the model fit
phi	list of truncated power series spline bases for the coefficient functions
psi	list of principal components basis for the functional predictors
varBetaHat	list containing covariance matrices for the estimated coefficient functions
Bounds	list of bounds of a 95% confidence interval for the estimated coefficient functions

### Author(s)

## End(Not run)

```

mfpca.sc

*Multilevel functional principal components analysis by smoothed covariance*

## Description

Decomposes functional observations using functional principal components analysis. A mixed model framework is used to estimate scores and obtain variance estimates.

## Usage

```

mfpca.sc(Y = NULL, id = NULL, visit = NULL, twoway = FALSE,
  argvals = NULL, nbasis = 10, pve = 0.99, npc = NULL,
  makePD = FALSE, center = TRUE, cov.est.method = 2,
  integration = "trapezoidal")

```

## Arguments

Y,	The user must supply a matrix of functions on a regular grid
id	Must be supplied, a vector containing the id information used to identify clusters
visit	A vector containing information used to identify visits. Defaults to NULL.
twoway	logical, indicating whether to carry out twoway ANOVA and calculate visit-specific means. Defaults to FALSE.
argvals	function argument.
nbasis	number of B-spline basis functions used for estimation of the mean function and bivariate smoothing of the covariance surface.
pve	proportion of variance explained: used to choose the number of principal components.
npc	prespecified value for the number of principal components (if given, this overrides pve).

makePD	logical: should positive definiteness be enforced for the covariance surface estimate? Defaults to FALSE Only FALSE is currently supported.
center	logical: should an estimated mean function be subtracted from Y? Set to FALSE if you have already demeaned the data using your favorite mean function estimate.
cov.est.method	covariance estimation method. If set to 1, a one-step method that applies a bivariate smooth to the $y(s_1)y(s_2)$ values. This can be very slow. If set to 2 (the default), a two-step method that obtains a naive covariance estimate which is then smoothed. 2 is currently supported.
integration	quadrature method for numerical integration; only "trapezoidal" is currently supported.

### Details

This function computes a multilevel FPC decomposition for a set of observed curves, which may be sparsely observed and/or measured with error. A mixed model framework is used to estimate level 1 and level 2 scores.

MFPCA was proposed in Di et al. (2009), with variations for MFPCA with sparse data in Di et al. (2014). mfPCA.sc uses penalized splines to smooth the covariance functions, as Described in Di et al. (2009) and Goldsmith et al. (2013).

### Value

An object of class mfPCA containing:

Yhat	FPC approximation (projection onto leading components) of Y, estimated curves for all subjects and visits
Yhat.subject	estimated subject specific curves for all subjects
Y	the observed data
scores	$n \times npc$ matrix of estimated FPC scores for level1 and level2.
mu	estimated mean function (or a vector of zeroes if center==FALSE).
efunctions	$d \times npc$ matrix of estimated eigenfunctions of the functional covariance, i.e., the FPC basis functions for levels 1 and 2.
evalues	estimated eigenvalues of the covariance operator, i.e., variances of FPC scores for levels 1 and 2.
npc	number of FPCs: either the supplied npc, or the minimum number of basis functions needed to explain proportion pve of the variance in the observed curves for levels 1 and 2.
sigma2	estimated measurement error variance.
eta	the estimated visit specific shifts from overall mean.

model.matrix.pffr	<i>Obtain model matrix for a pffr fit</i>
-------------------	---

---

## Description

Obtain model matrix for a pffr fit

## Usage

```
## S3 method for class 'pffr'
model.matrix(object, ...)
```

## Arguments

object	a fitted pffr-object
...	other arguments, passed to <a href="#">predict.gam</a> .

## Value

A model matrix

## Author(s)

Fabian Scheipl

---

ols\_cs

*Cross-sectional FoSR using GLS*

---

### Description

Fitting function for function-on-scalar regression for cross-sectional data. This function estimates model parameters using GLS: first, an OLS estimate of spline coefficients is estimated; second, the residual covariance is estimated using an FPC decomposition of the OLS residual curves; finally, a GLS estimate of spline coefficients is estimated. Although this is in the ‘BayesFoSR’ package, there is nothing Bayesian about this FoSR.

### Usage

```
ols_cs(formula, data = NULL, Kt = 5, basis = "bs", verbose = TRUE)
```

### Arguments

formula	a formula indicating the structure of the proposed model.
data	an optional data frame, list or environment containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which the function is called.
Kt	number of spline basis functions used to estimate coefficient functions
basis	basis type; options are "bs" for b-splines and "pbs" for periodic b-splines
verbose	logical defaulting to TRUE – should updates on progress be printed?

---

pco\_predict\_preprocess

*Make predictions using pco basis terms*

---

### Description

This function performs the necessary preprocessing for making predictions with [gam](#) models that include [pco](#) basis terms. The function `pco_predict_preprocess` builds a `data.frame` (or augments an existing one) to be used with the usual `predict` function.

**Usage**

```
pco_predict_preprocess(model, newdata = NULL, dist_list)
```

**Arguments**

model	a fitted <a href="#">gam</a> model with at least one term of class "pco.smooth".
newdata	data frame including the new values for any non- <a href="#">pco</a> terms in the original fit. If there were none, this can be left as NULL.
dist_list	a list of $n \times n^*$ matrices, one per <a href="#">pco</a> term in the model, giving the distances from the $n^*$ prediction points to the $n$ design points (original observations). List entry names should correspond to the names of the terms in the model (e.g., if the model includes a $s(x)$ term, <code>dist_list</code> must include an element named "x").

**Details**

Models with [pco](#) basis terms are fitted by inputting distances among the observations and then regressing (with a ridge penalty) on leading principal coordinates arising from these distances. To perform prediction, we must input the distances from the new data points to the original points, and then "insert" the former into the principal coordinate space by the interpolation method of Gower (1968) (see also Miller, 2012).

An example of how to use this function in practice is shown in [smooth.construct.pco.smooth.spec](#).

**Value**

a [data.frame](#) with the coordinates for the new data inserted into principal coordinate space, in addition to the supplied `newdata` if this was non-NULL. This can be used as the `newdata` argument in a call to [predict.gam](#).

---

pcrc	<i>pcrc-creator for functional principal component-based functional random intercepts.</i>
------	--

---

### Description

pcrc-creator for functional principal component-based functional random intercepts.

### Usage

```
pcrc(id, efunctions, evalues, yind, ...)
```

### Arguments

id	grouping variable a factor
efunctions	matrix of eigenfunction evaluations on gridpoints yind (<length of yind> x <no. of used eigenfunctions>)
evalues	eigenvalues associated with efunctions
yind	vector of gridpoints on which efunctions are evaluated.
...	not used

### Value

a list used internally for constructing an appropriate call to `mgcv::gam`

### Details

Fits functional random intercepts  $B_i(t)$  for a grouping variable `id` using as a basis the functions  $\phi_m(t)$  in `efunctions` with variances  $\lambda_m$  in `evalues`:  $B_i(t) \approx \sum_m^M \phi_m(t) \delta_{im}$  with independent  $\delta_{im} \sim N(0, \sigma^2 \lambda_m)$ , where  $\sigma^2$  is (usually) estimated and controls the overall contribution of the  $B_i(t)$  while the relative importance of the  $M$  basisfunctions is controlled by the supplied variances `lambda_m`. Can be used to model smooth residuals if `id` is simply an index of observations. Differing from random effects in `mgcv`, these effects are estimated under a "sum-to-zero-for-each-t"-constraint.

`efunctions` and `evalues` are typically eigenfunctions and eigenvalues of an estimated covariance operator for the functional process to be modeled, i.e., they are a functional principal components basis.

plot(m0, select=1, main="m0", ylim=range(Y))
lines(t, int[1,], col=rgb(1,0,0,.5))

## End(Not run)

```

## Description

Defines a term  $\int_T \beta(t) X_i(t) dt$  for inclusion in a [pfr](#) formula, where  $\beta(t)$  is estimated with structured penalties (Randolph et al., 2012).

**Usage**

```
peer(X, argvals = NULL, pentype = "RIDGE", Q = NULL, phia = 10^3,
     L = NULL, ...)
```

**Arguments**

X	functional predictors, typically expressed as an N by J matrix, where N is the number of columns and J is the number of evaluation points. May include missing/sparse functions, which are indicated by NA values. Alternatively, can be an object of class "fd"; see <a href="#">fd</a> .
argvals	indices of evaluation of X, i.e. $(t_{i1}, \dots, t_{iJ})$ for subject $i$ . May be entered as either a length-J vector, or as an N by J matrix. Indices may be unequally spaced. Entering as a matrix allows for different observations times for each subject. If NULL, defaults to an equally-spaced grid between 0 or 1 (or within $X\$basis\$rangeval$ if X is a fd object.)
pentype	the type of penalty to apply, one of "RIDGE", "D", "DECOMP", or "USER"; see Details.
Q	matrix $Q$ used for <code>pentype="DECOMP"</code> ; see Details.
phia	scalar $a$ used for <code>pentype="DECOMP"</code> ; see Details.
L	user-supplied penalty matrix for <code>pentype="USER"</code> ; see Details.
...	additional arguments to be passed to <code>lf</code> (and then possibly <code>s</code> ). Arguments processed by <code>lf</code> include, for example, integration for specifying the method of numerical integration. Arguments processed by <code>s</code> include information related to basis and penalization, such as <code>m</code> for specifying the order of the difference penalty; See Details. <code>xt</code> -argument is not allowed for <code>peer</code> -terms and will cause an error.

**Details**

`peer` is a wrapper for `lf`, which defines linear functional predictors for any type of basis. It simply calls `lf` with the appropriate options for the `peer` basis and penalty construction. The type of penalty is determined by the `pentype` argument. There are four types of penalties available:

1. `pentype=="RIDGE"` for a ridge penalty, the default
2. `pentype=="D"` for a difference penalty. The order of the difference penalty may be specified by supplying an `m` argument (default is 2).
3. `pentype=="DECOMP"` for a decomposition-based penalty,  $bP_Q + a(I - P_Q)$ , where  $P_Q = Q^t(QQ^t)^{-1}Q$ . The  $Q$  matrix must be specified by `Q`, and the scalar  $a$  by `phia`. The number of columns of  $Q$  must be equal to the length of the data. Each row represents a basis function where the functional predictor is expected to lie, according to prior belief.
4. `pentype=="USER"` for a user-specified penalty matrix, supplied by the `L` argument.

The original stand-alone implementation by Madan Gopal Kundu is available in [peer\\_old](#).

PEER.Sim

*Simulated longitudinal data with functional predictor and scalar response, and structural information associated with predictor function*

---

## Description

PEER.Sim contains simulated observations from 100 subjects, each observed at 4 distinct time-points. At each timepoint bumpy predictor profile is generated randomly and the scalar response

variable is generated considering a time-varying regression function and subject intercept. Accompanying the functional predictor and scalar response are the subject ID numbers and time of measurements.

### Format

The data frame `PEER.Sim` is made up of subject ID number (`id`), subject-specific time of measurement (`t`), functional predictor profile (`W.1-W.100`) and scalar response (`Y`)

### Details

`Q` represents the  $7 \times 100$  matrix where each row provides structural information about the functional predictor profile for data `PEER.Sim`. For specific details about the simulation and `Q` matrix, please refer to Kundu et. al. (2012).

### References

---

peer\_old

*Functional Models with Structured Penalties*

---

### Description

Implements functional model with structured penalties (Randolph et al., 2012) with scalar outcome and single functional predictor through mixed model equivalence.

### Usage

```
peer_old(Y, funcs, argvals = NULL, pentype = "Ridge", L.user = NULL,
        Q = NULL, phia = 10^3, se = FALSE, ...)
```

### Arguments

<code>Y</code>	vector of all outcomes
<code>funcs</code>	matrix containing observed functional predictors as rows. Rows with NA and Inf values will be deleted.
<code>argvals</code>	matrix (or vector) of indices of evaluations of $X_i(t)$ ; i.e. a matrix with $i$ th row $(t_{i1}, \dots, t_{iJ})$
<code>pentype</code>	type of penalty. It can be either decomposition based penalty (DECOMP) or ridge (RIDGE) or second-order difference penalty (D2) or any user defined penalty (USER). For decomposition based penalty user need to specify <code>Q</code> matrix in <code>Q</code> argument (see details). For user defined penalty user need to specify <code>L</code> matrix in <code>L</code> argument (see details). For Ridge and second-order difference penalty, specification for arguments <code>L</code> and <code>Q</code> will be ignored. Default is RIDGE.

L.user	penalty matrix. Need to be specified with pentype='USER'. Number of columns need to be equal with number of columns of matrix specified to funcs. Each row represents a constraint on functional predictor. This argument will be ignored when value of pentype is other than USER.
Q	Q matrix to derive decomposition based penalty. Need to be specified with pentype='DECOMP'. Number of columns need to be equal with number of columns of matrix specified to funcs. Each row represents a basis function where functional predictor is expected lie according to prior belief. This argument will be ignored when value of pentype is other than DECOMP.
phia	Scalar value of a in decomposition based penalty. Need to be specified with pentype='DECOMP'.
se	logical; calculate standard error when TRUE.
...	additional arguments passed to the <code>lme</code> function.

### Details

If there are any missing or infinite values in Y, and funcs, the corresponding row (or observation) will be dropped. Neither Q nor L may contain missing or infinite values.

`peer_old()` fits the following model:

$$y_i = \int W_i(s)\gamma(s)ds + \epsilon_i$$

where  $\epsilon_i \sim N(0, \sigma^2)$ . For all the observations, predictor function  $W_i(s)$  is evaluated at K sampling points. Here,  $\gamma(s)$  denotes the regression function.

Values of  $y_i$  and  $W_i(s)$  are passed through argument Y and funcs, respectively. Number of elements or rows in Y and funcs need to be equal.

The estimate of regression functions  $\gamma(s)$  is obtained as penalized estimated. Following 3 types of penalties can be used:

i. Ridge:  $I_K$

ii. Second-order difference:  $[d_{i,j}]$  with  $d_{i,i} = d_{i,i+2} = 1, d_{i,i+1} = -2$ , otherwise  $d_{i,i} = 0$

iii. Decomposition based penalty:  $bP_Q + a(I - P_Q)$  where  $P_Q = Q^T(QQ^T)^{-1}Q$

For Decomposition based penalty user need to specify pentype='DECOMP' and associated Q matrix need to be passed through Q argument.

Alternatively, user can pass directly penalty matrix through argument L. For this user need to specify pentype='USER' and associated L matrix need to be passed through L argument.

Default penalty is Ridge penalty and user needs to specify RIDGE. For second-order difference penalty, user needs to specify D2.

### Value

a list containing:

fit	result of the call to <code>lme</code>
fitted.vals	predicted outcomes
Gamma	estimates with standard error for regression function
GammaHat	estimates of regression function

se.Gamma	standard error associated with GammaHat
AIC	AIC value of fit (smaller is better)
BIC	BIC value of fit (smaller is better)
logLik	(restricted) log-likelihood at convergence
lambda	estimates of smoothing parameter
N	number of subjects
K	number of Sampling points in functional predictor
sigma	estimated within-group error standard deviation.

pffr

*Penalized flexible functional regression***Description**

Implements additive regression for functional and scalar covariates and functional responses. This function is a wrapper for mgcv's `gam` and its siblings to fit models of the general form  $E(Y_i(t)) = g(\mu(t) + \int X_i(s)\beta(s,t)ds + f(z_{1i},t) + f(z_{2i}) + z_{3i}\beta_3(t) + \dots)$  with a functional (but not necessarily continuous) response  $Y(t)$ , response function  $g$ , (optional) smooth intercept  $\mu(t)$ , (multiple) functional covariates  $X(t)$  and scalar covariates  $z_1, z_2$ , etc.

**Usage**

```

pffr(formula, yind, data = NULL, ydata = NULL, algorithm = NA,
      method = "REML", tensortype = c("ti", "t2"), bs.yindex = list(bs =
        "ps", k = 5, m = c(2, 1)), bs.int = list(bs = "ps", k = 20, m = c(2,
        1)), ...)

```

**Arguments**

formula	a formula with special terms as for <code>gam</code> , with additional special terms <code>ff()</code> , <code>sff()</code> , <code>ffpc()</code> , <code>pcrc()</code> and <code>c()</code> .
yind	a vector with length equal to the number of columns of the matrix of functional responses giving the vector of evaluation points $(t_1, \dots, t_G)$ . If not supplied, yind is set to <code>1:ncol(&lt;response&gt;)</code> .
data	an (optional) <code>data.frame</code> containing the data. Can also be a named list for regular data. Functional covariates have to be supplied as <code>&lt;no. of observations&gt;</code> by <code>&lt;no. of evaluations&gt;</code> matrices, i.e. each row is one functional observation.
ydata	an (optional) <code>data.frame</code> supplying functional responses that are not observed on a regular grid. See Details.

algorithm	the name of the function used to estimate the model. Defaults to <code>gam</code> if the matrix of functional responses has less than $2e5$ data points and to <code>bam</code> if not. <code>'gamm'</code> , <code>'gamm4'</code> and <code>'jagam'</code> are valid options as well. See Details for <code>'gamm4'</code> and <code>'jagam'</code> .
method	Defaults to "REML"-estimation, including of unknown scale. If <code>algorithm="bam"</code> , the default is switched to "fREML". See <code>gam</code> and <code>bam</code> for details.
tensorstype	which typ of tensor product splines to use. One of "ti" or "t2", defaults to ti. t2-type terms do not enforce the more suitable special constraints for functional regression, see Details.
bs.yindex	a named (!) list giving the parameters for spline bases on the index of the functional response. Defaults to <code>list(bs="ps",k=5,m=c(2,1))</code> , i.e. 5 cubic B-splines bases with first order difference penalty.
bs.int	a named (!) list giving the parameters for the spline basis for the global functional intercept. Defaults to <code>list(bs="ps",k=20,m=c(2,1))</code> , i.e. 20 cubic B-splines bases with first order difference penalty.
...	additional arguments that are valid for <code>gam</code> , <code>bam</code> , <code>'gamm4'</code> or <code>'jagam'</code> . subset is not implemented.

### Value

A fitted `pffr`-object, which is a `gam`-object with some additional information in an `pffr`-entry. If `algorithm` is "gamm" or "gamm4", only the `$gam` part of the returned list is modified in this way. Available methods/functions to postprocess fitted models: `summary.pffr`, `plot.pffr`, `coef.pffr`, `fitted.pffr`, `residuals.pffr`, `predict.pffr`, `model.matrix.pffr`, `qq.pffr`, `pffr.check`. If `algorithm` is "jagam", only the location of the model file and the usual `jagam`-object are returned, you have to run the sampler yourself.

### Details

The routine can estimate

1. linear functional effects of scalar (numeric or factor) covariates that vary smoothly over  $t$  (e.g.  $z_{1i}\beta_1(t)$ , specified as `~z1`),
2. nonlinear, and possibly multivariate functional effects of (one or multiple) scalar covariates  $z$  that vary smoothly over the index  $t$  of  $Y(t)$  (e.g.  $f(z_{2i}, t)$ , specified in the formula simply as `~s(z2)`)
3. (nonlinear) effects of scalar covariates that are constant over  $t$  (e.g.  $f(z_{3i})$ , specified as `~c(s(z3))`, or  $\beta_3 z_{3i}$ , specified as `~c(z3)`),
4. function-on-function regression terms (e.g.  $\int X_i(s)\beta(s, t)ds$ , specified as `~ff(X, yindex=t, xindex=s)`, see `ff`). Terms given by `sff` and `ffpc` provide nonlinear and FPC-based effects of functional covariates, respectively.
5. concurrent effects of functional covariates  $X$  measured on the same grid as the response are specified as follows: `~s(x)` for a smooth, index-varying effect  $f(X(t), t)$ , `~x` for a linear index-varying effect  $X(t)\beta(t)$ , `~c(s(x))` for a constant nonlinear effect  $f(X(t))$ , `~c(x)` for a constant linear effect  $X(t)\beta$ .

6. Smooth functional random intercepts  $b_{0g(i)}(t)$  for a grouping variable  $g$  with levels  $g(i)$  can be specified via  $\sim s(g, bs="re")$ , functional random slopes  $u_i b_{1g(i)}(t)$  in a numeric variable  $u$  via  $\sim s(g, u, bs="re")$ . Scheipl, Staicu, Greven (2013) contains code examples for modeling correlated functional random intercepts using `mrf`-terms.

Use the `c()`-notation to denote model terms that are constant over the index of the functional response.

Internally, univariate smooth terms without a `c()`-wrapper are expanded into bivariate smooth terms in the original covariate and the index of the functional response. Bivariate smooth terms (`s()`, `te()` or `t2()`) without a `c()`-wrapper are expanded into trivariate smooth terms in the original covariates and the index of the functional response. Linear terms for scalar covariates or categorical covariates are expanded into varying coefficient terms, varying smoothly over the index of the functional response. For factor variables, a separate smooth function with its own smoothing parameter is estimated for each level of the factor.

The marginal spline basis used for the index of the the functional response is specified via the `global` argument `bs.yindex`. If necessary, this can be overridden for any specific term by supplying a `bs.yindex`-argument to that term in the formula, e.g.  $\sim s(x, bs.yindex=list(bs="tp", k=7))$  would yield a tensor product spline over  $x$  and the index of the response in which the marginal basis for the index of the response are 7 cubic thin-plate spline functions (overriding the global default for the basis and penalty to the index of the response given by the `global` `bs.yindex`-argument). Use  $\sim -1 + c(1) + \dots$  to specify a model with only a constant and no functional intercept.

The functional covariates have to be supplied as a  $n$  by `<no. of evaluations>` matrices, i.e. each row is one functional observation. For data on a regular grid, the functional response is supplied in the same format, i.e. as a matrix-valued entry in `data`, which can contain missing values.

If the functional responses are *sparse or irregular* (i.e., not evaluated on the same evaluation points across all observations), the `ydata`-argument can be used to specify the responses: `ydata` must be a `data.frame` with 3 columns called `' .obs '`, `' .index '`, `' .value '` which specify which curve the point belongs to (`' .obs '=i`), at which  $t$  it was observed (`' .index '=t`), and the observed value (`' .value '=Yi(t)`). Note that the vector of unique sorted entries in `ydata$.obs` must be equal to `rownames(data)` to ensure the correct association of entries in `ydata` to the corresponding rows of `data`. For both regular and irregular functional responses, the model is then fitted with the data in long format, i.e., for data on a grid the rows of the matrix of the functional response evaluations  $Y_i(t)$  are stacked into one long vector and the covariates are expanded/repeated correspondingly. This means the models get quite big fairly fast, since the effective number of rows in the design matrix is number of observations times number of evaluations of  $Y(t)$  per observation.

Note that `pffr` does not use `mgcv`'s default identifiability constraints (i.e.,  $\sum_{i,t} \hat{f}(z_i, x_i, t) = 0$  or  $\sum_{i,t} \hat{f}(x_i, t) = 0$ ) for tensor product terms whose marginals include the index  $t$  of the functional response. Instead,  $\sum_i \hat{f}(z_i, x_i, t) = 0$  for all  $t$  is enforced, so that effects varying over  $t$  can be interpreted as local deviations from the global functional intercept. This is achieved by using `ti`-terms with a suitably modified `mc`-argument. Note that this is not possible if `algorithm='gam4'` since only `t2`-type terms can then be used and these modified constraints are not available for `t2`. We recommend using centered scalar covariates for terms like  $z\beta(t)$  (`~z`) and centered functional

covariates with  $\sum_i X_i(t) = 0$  for all  $t$  in ff-terms so that the global functional intercept can be interpreted as the global mean function.

The family-argument can be used to specify all of the response distributions and link functions described in `family.mgcv`. Note that family = "gaulss" is treated in a special way: Users can supply the formula for the variance by supplying a special argument `varformula`, but this is not modified in the way that the formula-argument is but handed over to the fitter directly, so this is for expert use only. If `varformula` is not given, `pffr` will use the parameters from argument `bs.int` to define a spline basis along the index of the response, i.e., a smooth variance function over  $t$  for responses  $Y(t)$ .

pffr.check

*Some diagnostics for a fitted pffr model***Description**

This is simply a wrapper for [gam.check\(\)](#).

**Usage**

```

pffr.check(b, old.style = FALSE, type = c("deviance", "pearson",
  "response"), k.sample = 5000, k.rep = 200, rep = 0, level = 0.9,
  rl.col = 2, rep.col = "gray80", ...)

```

**Arguments**

b	a fitted <a href="#">pffr</a> -object
old.style	If you want old fashioned plots, exactly as in Wood, 2006, set to TRUE.
type	type of residuals, see <a href="#">residuals.gam</a> , used in all plots.
k.sample	Above this k testing uses a random sub-sample of data.

k.rep	how many re-shuffles to do to get p-value for k testing.
rep	passed to <code>qq.gam</code> when <code>old.style</code> is FALSE.
level	passed to <code>qq.gam</code> when <code>old.style</code> is FALSE.
rl.col	passed to <code>qq.gam</code> when <code>old.style</code> is FALSE.
rep.col	passed to <code>qq.gam</code> when <code>old.style</code> is FALSE.
...	extra graphics parameters to pass to plotting functions.

pffrGLS

*Penalized function-on-function regression with non-i.i.d. residuals***Description**

Implements additive regression for functional and scalar covariates and functional responses. This function is a wrapper for `mgcv`'s `gam` and its siblings to fit models of the general form  $Y_i(t) = \mu(t) + \int X_i(s)\beta(s,t)ds + f(z_{1i},t) + f(z_{2i}) + z_{3i}\beta_3(t) + \dots + E_i(t)$  with a functional (but not necessarily continuous) response  $Y(t)$ , (optional) smooth intercept  $\mu(t)$ , (multiple) functional covariates  $X(t)$  and scalar covariates  $z_1, z_2$ , etc. The residual functions  $E_i(t) \sim GP(0, K(t, t'))$  are assumed to be i.i.d. realizations of a Gaussian process. An estimate of the covariance operator  $K(t, t')$  evaluated on `yind` has to be supplied in the `hatSigma`-argument.

**Usage**

```
pffrGLS(formula, yind, hatSigma, algorithm = NA, method = "REML",
         tensortype = c("te", "t2"), bs.yindex = list(bs = "ps", k = 5, m =
         c(2, 1)), bs.int = list(bs = "ps", k = 20, m = c(2, 1)),
         cond.cutoff = 500, ...)
```

**Arguments**

formula	a formula with special terms as for <code>gam</code> , with additional special terms <code>ff()</code> and <code>c()</code> . See <code>pffr</code> .
yind	a vector with length equal to the number of columns of the matrix of functional responses giving the vector of evaluation points $(t_1, \dots, t_G)$ . see <code>pffr</code>
hatSigma	(an estimate of) the within-observation covariance (along the responses' index), evaluated at <code>yind</code> . See Details.
algorithm	the name of the function used to estimate the model. Defaults to <code>gam</code> if the matrix of functional responses has less than $2e5$ data points and to <code>bam</code> if not. "gamm" (see <code>gamm</code> ) and "gamm4" (see <code>gamm4</code> ) are valid options as well.
method	See <code>pffr</code>
tensortype	See <code>pffr</code>
bs.yindex	See <code>pffr</code>
bs.int	See <code>pffr</code>
cond.cutoff	if the condition number of <code>hatSigma</code> is greater than this, <code>hatSigma</code> is made "more" positive-definite via <code>nearPD</code> to ensure a condition number equal to <code>cond.cutoff</code> . Defaults to 500.
...	additional arguments that are valid for <code>gam</code> or <code>bam</code> . See <code>pffr</code> .

**Value**

a fitted pffr-object, see [pffr](#).

**Details**

Note that `hatSigma` has to be positive definite. If `hatSigma` is close to positive *semi*-definite or badly conditioned, estimated standard errors become unstable (typically much too small). `pffrGLS` will try to diagnose this and issue a warning. The danger is especially big if the number of functional observations is smaller than the number of gridpoints (i.e. `length(yind)`), since the raw covariance estimate will not have full rank.

Please see [pffr](#) for details on model specification and implementation.

THIS IS AN EXPERIMENTAL VERSION AND NOT WELL TESTED YET – USE AT YOUR OWN RISK.

pffrSim

*Simulate example data for pffr*

---

**Description**

Simulates example data for [pffr](#) from a variety of terms. Scenario "all" generates data from a complex multivariate model

$$Y_i(t) = \mu(t) + \int X_{1i}(s)\beta_1(s,t)ds + xlin\beta_3(t) + f(xte1, xte2) + f(xsmoo, t) + \beta_4 xconst + f(xfactor, t) + \epsilon_i(t)$$

. Scenarios "int", "ff", "lin", "te", "smoo", "const", "factor", generate data from simpler models containing only the respective term(s) in the model equation given above. Specifying a vector-valued scenario will generate data from a combination of the respective terms. Sparse/irregular response trajectories can be generated by setting `propmissing` to something greater than 0 (and smaller than 1). The return object then also includes a `ydata`-item with the sparsified data.

**Usage**

```
pffrSim(scenario = "all", n = 100, nxgrid = 40, nygrid = 60,
        SNR = 10, propmissing = 0, limits = NULL)
```

**Arguments**

scenario	see Description
n	number of observations
nxgrid	number of evaluation points of functional covariates
nygrid	number of evaluation points of the functional response
SNR	the signal-to-noise ratio for the generated data: empirical variance of the additive predictor divided by variance of the errors.
propmissing	proportion of missing data in the response, default = 0. See Details.
limits	a function that defines an integration range, see <a href="#">ff</a>

**Details**

See source code for details.

**Value**

a named list with the simulated data, and the true components of the predictor etc as attributes.

---

pfr

*Penalized Functional Regression*

---

**Description**

Implements various approaches to penalized scalar-on-function regression. These techniques include Penalized Functional Regression (Goldsmith et al., 2011), Longitudinal Penalized Functional Regression (Goldsmith, et al., 2012), Functional Principal Component Regression (Reiss and Ogden, 2007), Partially Empirical Eigenvectors for Regression (Randolph et al., 2012), Functional Generalized Additive Models (McLean et al., 2013), and Variable-Domain Functional Regression (Gellar et al., 2014). This function is a wrapper for mgcv's [gam](#) and its siblings to fit models with a scalar (but not necessarily continuous) response.

**Usage**

```
pfr(formula = NULL, fitter = NA, method = "REML", ...)
```

**Arguments**

formula	a formula that could contain any of the following special terms: <a href="#">lf()</a> , <a href="#">af()</a> , <a href="#">lf.vd()</a> , <a href="#">peer()</a> , <a href="#">fpc()</a> , or <a href="#">re()</a> ; also mgcv's <a href="#">s()</a> , <a href="#">te()</a> , or <a href="#">t2()</a> .
fitter	the name of the function used to estimate the model. Defaults to <a href="#">gam</a> if the matrix of functional responses has less than 2e5 data points and to <a href="#">bam</a> if not. "gamm" (see <a href="#">gamm</a> ) and "gamm4" (see <a href="#">gamm4</a> ) are valid options as well.
method	The smoothing parameter estimation method. Default is "REML". For options, see <a href="#">gam</a> .

... additional arguments that are valid for `gam` or `bam`. These include data and family to specify the input data and outcome family, as well as many options to control the estimation.

### Value

A fitted pfr-object, which is a `gam`-object with some additional information in a `$pfr`-element. If fitter is "gamm" or "gamm4", only the `$gam` part of the returned list is modified in this way.

### Warning

Binomial responses should be specified as a numeric vector rather than as a matrix or a factor.

## End(Not run)

```

pfr\_old

*Penalized Functional Regression (old version)***Description**

This code implements the function `pfr()` available in `refund` 0.1-11. It is included to maintain backwards compatibility.

Functional predictors are entered as a matrix or, in the case of multiple functional predictors, as a list of matrices using the `funcs` argument. Missing values are allowed in the functional predictors, but it is assumed that they are observed over the same grid. Functional coefficients and confidence bounds are returned as lists in the same order as provided in the `funcs` argument, as are principal component and spline bases. Increasing values of `nbasis` will increase computational time and the values of `nbasis`, `kz`, and `kb` in relation to each other may need to be adjusted in application-specific ways.

**Usage**

```
pfr_old(Y, subj = NULL, covariates = NULL, funcs, kz = 10, kb = 30,
        nbasis = 10, family = "gaussian", method = "REML",
        smooth.option = "fpca.sc", pve = 0.99, ...)
```

**Arguments**

<code>Y</code>	vector of all outcomes over all visits
<code>subj</code>	vector containing the subject number for each observation
<code>covariates</code>	matrix of scalar covariates
<code>funcs</code>	matrix, or list of matrices, containing observed functional predictors as rows. NA values are allowed.
<code>kz</code>	can be NULL; can be a scalar, in which case this will be the dimension of principal components basis for each and every observed functional predictors; can be a vector of length equal to the number of functional predictors, in which case each element will correspond to the dimension of principal components basis for the corresponding observed functional predictors
<code>kb</code>	dimension of the B-spline basis for the coefficient function (note: this is a change from versions 0.1-7 and previous)
<code>nbasis</code>	passed to <code>refund::fpca.sc</code> (note: using <code>fpca.sc</code> is a change from versions 0.1-7 and previous)
<code>family</code>	generalized linear model family
<code>method</code>	method for estimating the smoothing parameters; defaults to REML
<code>smooth.option</code>	method to do FPC decomposition on the predictors. Two options available – “ <code>fpca.sc</code> ” or “ <code>fpca.face</code> ”. If using “ <code>fpca.sc</code> ”, a number less than 35 for <code>nbasis</code> should be used while if using “ <code>fpca.face</code> ”, 35 or more is recommended.
<code>pve</code>	proportion of variance explained used to choose the number of principal components to be included in the expansion.
<code>...</code>	additional arguments passed to <code>gam</code> to fit the regression model.

**Value**

<code>fit</code>	result of the call to <code>gam</code>
<code>fitted.vals</code>	predicted outcomes
<code>fitted.vals.level.0</code>	predicted outcomes at population level
<code>fitted.vals.level.1</code>	predicted outcomes at subject-specific level (if applicable)
<code>betaHat</code>	list of estimated coefficient functions
<code>beta.covariates</code>	parameter estimates for scalar covariates
<code>varBetaHat</code>	list containing covariance matrices for the estimated coefficient functions
<code>Bounds</code>	list of bounds of a pointwise 95% confidence interval for the estimated coefficient functions
<code>X</code>	design matrix used in the model fit
<code>D</code>	penalty matrix used in the model fit
<code>phi</code>	list of B-spline bases for the coefficient functions
<code>psi</code>	list of principal components basis for the functional predictors
<code>C</code>	stacked row-specific principal component scores
<code>J</code>	transpose of <code>psi</code> matrix multiplied by <code>phi</code>
<code>CJ</code>	<code>C</code> matrix multiplied <code>J</code>
<code>Z1</code>	design matrix of random intercepts
<code>subj</code>	subject identifiers as specified by user
<code>fixed.mat</code>	the fixed effects design matrix of the pfr as a mixed model
<code>rand.mat</code>	the fixed effects design matrix of the pfr as a mixed model
<code>N_subj</code>	the number of unique subjects, if <code>subj</code> is specified
<code>p</code>	number of scalar covariates
<code>N.pred</code>	number of functional covariates
<code>kz</code>	as specified
<code>kz.adj</code>	For <code>smooth.option="fpca.sc"</code> , will be same as <code>kz</code> (or a vector of repeated values of the specified scalar <code>kz</code> ). For <code>smooth.option="fpca.face"</code> , will be the corresponding number of principal components for each functional predictor as determined by <code>fpca.face</code> ; will be less than or equal to <code>kz</code> on an elemental-wise level.
<code>kb</code>	as specified
<code>nbasis</code>	as specified
<code>totD</code>	number of penalty matrices created for <code>mgcv::gam</code>
<code>funcs</code>	as specified
<code>covariates</code>	as specified
<code>smooth.option</code>	as specified

**Warning**

Binomial responses should be specified as a numeric vector rather than as a matrix or a factor.

```

---

plot.fosr

*Default plotting of function-on-scalar regression objects*

---

### Description

Plots the coefficient function estimates produced by `fosr()`.

### Usage

```
## S3 method for class 'fosr'
plot(x, split = NULL, titles = NULL, xlabel = "",
     ylabel = "Coefficient function", set.mfrow = TRUE, ...)
```

### Arguments

<code>x</code>	an object of class " <code>fosr</code> ".
<code>split</code>	value, or vector of values, at which to divide the set of coefficient functions into groups, each plotted on a different scale. E.g., if set to 1, the first function is plotted on one scale, and all others on a different (common) scale. If <code>NULL</code> , all functions are plotted on the same scale.
<code>titles</code>	character vector of titles for the plots produced, e.g., names of the corresponding scalar predictors.
<code>xlabel</code>	label for the x-axes of the plots.
<code>ylabel</code>	label for the y-axes of the plots.
<code>set.mfrow</code>	logical value: if <code>TRUE</code> , the function will try to set an appropriate value of the <code>mfrow</code> parameter for the plots. Otherwise you may wish to set <code>mfrow</code> outside the function call.
<code>...</code>	graphical parameters (see <code>par</code> ) for the plot.

`plot.fosr.vs`*Plot for Function-on Scalar Regression with variable selection*

---

**Description**

Given a "`fosr.vs`" object, produces a figure of estimated coefficient functions.

**Usage**

```
## S3 method for class 'fosr.vs'  
plot(x, ...)
```

**Arguments**

`x` an object of class "`fosr.vs`".  
`...` additional arguments.

**Value**

a figure of estimated coefficient functions.

**Author(s)**

Yakuan Chen <yc2641@cumc.columbia.edu>

**See Also**

## End(Not run)

```

---

plot.fpcr

*Default plotting for functional principal component regression output*

---

### Description

Inputs an object created by `fpcr`, and plots the estimated coefficient function.

### Usage

```

## S3 method for class 'fpcr'
plot(x, se = TRUE, col = 1, lty = c(1, 2, 2),
     xlab = "", ylab = "Coefficient function", ...)

```

### Arguments

<code>x</code>	an object of class <code>"fpcr"</code> .
<code>se</code>	if TRUE (the default), upper and lower lines are added at 2 standard errors (in the Bayesian sense; see Wood, 2006) above and below the coefficient function estimate. If a positive number is supplied, the standard error is instead multiplied by this number.
<code>col</code>	color for the line(s). This should be either a number, or a vector of length 3 for the coefficient function estimate, lower bound, and upper bound, respectively.
<code>lty</code>	line type(s) for the coefficient function estimate, lower bound, and upper bound.
<code>xlab, ylab</code>	x- and y-axis labels.
<code>...</code>	other arguments passed to the underlying plotting function.

**Value**

None; only a plot is produced.

---

plot.lpeer

*Plotting of estimated regression functions obtained through lpeer()*

---

**Description**

Plots the estimate of components of estimated regression function obtained from an [lpeer](#) object along with pointwise confidence bands.

**Usage**

```
## S3 method for class 'lpeer'  
plot(x, conf = 0.95, ...)
```

**Arguments**

x	object of class " <a href="#">lpeer</a> ".
conf	pointwise confidence level.
...	additional arguments passed to <a href="#">plot</a> .

**Details**

Pointwise confidence interval is displayed only if the user set `se=T` in the call to [lpeer](#), and does not reflect any multiplicity correction.

```
plot.pffr
```

```
Plot a pffr fit
```

---

**Description**

Plot a fitted pffr-object. Simply dispatches to `plot.gam`.

**Usage**

```
## S3 method for class 'pffr'
plot(x, ...)
```

**Arguments**

```
x          a fitted pffr-object
...        arguments handed over to plot.gam
```

**Value**

This function only generates plots.

**Author(s)**

Fabian Scheipl

---

`plot.pfr`*Plot a pfr object*

---

**Description**

This function plots the smooth coefficients of a pfr object. These include functional coefficients as well as any smooths of scalar covariates. The function dispatches to `pfr_plot.gam`, which is our local copy of `plot.gam` with some minor changes.

**Usage**

```
## S3 method for class 'pfr'  
plot(x, Qtransform = FALSE, ...)
```

**Arguments**

<code>x</code>	a fitted pfr-object
<code>Qtransform</code>	For additive functional terms, TRUE indicates the coefficient should be plotted on the quantile-transformed scale, whereas FALSE indicates the scale of the original data. Note this is different from the <code>Qtransform</code> argument of <code>af</code> , which specifies the scale on which the term is fit.
<code>...</code>	arguments handed over to <code>plot.gam</code>

**Value**

This function's main purpose is its side effect of generating plots. It also silently returns a list of the data used to produce the plots, which can be used to generate customized plots.

predict.fbps	<i>Prediction for fast bivariate P-spline (fbps)</i>
--------------	--

---

**Description**

Produces predictions given a `fbps` object and new data

**Usage**

```
## S3 method for class 'fbps'
predict(object, newdata, ...)
```

**Arguments**

<code>object</code>	an object returned by <code>fbps</code>
<code>newdata</code>	a data frame or list consisting of x and z values for which predicted values are desired. vectors of x and z need to be of the same length.
<code>...</code>	additional arguments.

**Value**

A list with components

<code>x</code>	a vector of x given in newdata
<code>z</code>	a vector of z given in newdata
<code>fitted.values</code>	a vector of fitted values corresponding to x and z given in newdata

---

predict.fgam

*Prediction from a fitted FGAM model*

---

## Description

Takes a fitted fgam-object produced by `fgam` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. This is a wrapper function for `predict.gam()`

## Usage

```

## S3 method for class 'fgam'
predict(object, newdata, type = "response",
        se.fit = FALSE, terms = NULL, PredOutOfRange = FALSE, ...)

```

## Arguments

object	a fitted fgam object as produced by <code>fgam</code>
newdata	a named list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. All variables provided to newdata should be in the format supplied to <code>fgam</code> , i.e., functional predictors must be supplied as matrices with each row corresponding to one observed function. Index variables for the functional covariates are reused from the fitted model object or alternatively can be supplied as attributes of the matrix of functional predictor values. Any variables in the model not specified in newdata are set to their average values from the data supplied during fitting the model
type	character; see <code>predict.gam</code> for details
se.fit	logical; see <code>predict.gam</code> for details
terms	character see <code>predict.gam</code> for details
PredOutOfRange	logical; if this argument is true then any functional predictor values in newdata corresponding to fgam terms that are greater[less] than the maximum[minimum] of the domain of the marginal basis for the rows of the tensor product smooth are set to the maximum[minimum] of the domain. If this argument is false, attempting to predict a value of the functional predictor outside the range of this basis produces an error
...	additional arguments passed on to <code>predict.gam</code>

**Value**

If `type == "lpmatrix"`, the design matrix for the supplied covariate values in long format. If `se == TRUE`, a list with entries `fit` and `se.fit` containing fits and standard errors, respectively. If `type == "terms"` or `"iterms"` each of these lists is a list of matrices of the same dimension as the response for newdata containing the linear predictor and its `se` for each term

Jonathan Gellar

---

predict.pffr

*Prediction for penalized function-on-function regression*

---

**Description**

Takes a fitted pffr-object produced by `pffr()` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. This is a wrapper function for `predict.gam()`.

**Usage**

```
## S3 method for class 'pffr'
predict(object, newdata, reformat = TRUE, type = "link",
        se.fit = FALSE, ...)
```

**Arguments**

object	a fitted pffr-object
newdata	A named list (or a data.frame) containing the values of the model covariates at which predictions are required. If no newdata is provided then predictions corresponding to the original data are returned. If newdata is provided then it must contain all the variables needed for prediction, in the format supplied to pffr, i.e., functional predictors must be supplied as matrices with each row corresponding to one observed function. See Details for more on index variables and prediction for models fit on irregular or sparse data.
reformat	logical, defaults to TRUE. Should predictions be returned in matrix form (default) or in the long vector shape returned by <code>predict.gam()</code> ?
type	see <code>predict.gam()</code> for details. Note that <code>type == "lpmatrix"</code> will force <code>reformat</code> to FALSE.
se.fit	see <code>predict.gam()</code>
...	additional arguments passed on to <code>predict.gam()</code>

**Details**

Index variables (i.e., evaluation points) for the functional covariates are reused from the fitted model object and cannot be supplied with `newdata`. Prediction is always for the entire index range of the responses as defined in the original fit. If the original fit was performed on sparse or irregular, non-gridded response data supplied via `pfr`'s `ydata`-argument and no `newdata` was supplied, this function will simply return fitted values for the original evaluation points of the response (in list form). If the original fit was performed on sparse or irregular data and `newdata` was supplied, the function will return predictions on the grid of evaluation points given in `object$pfr$yind`.

**Value**

If `type == "lpmatrix"`, the design matrix for the supplied covariate values in long format. If `se == TRUE`, a list with entries `fit` and `se.fit` containing fits and standard errors, respectively. If `type == "terms"` or `"iterms"` each of these lists is a list of matrices of the same dimension as the response for `newdata` containing the linear predictor and its `se` for each term.

---

predict.pfr

*Prediction from a fitted pfr model*

---

**Description**

Takes a fitted `pfr`-object produced by `pfr` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. This is a wrapper function for `predict.gam()`

**Usage**

```
## S3 method for class 'pfr'
predict(object, newdata, type = "response",
        se.fit = FALSE, terms = NULL, PredOutOfRange = FALSE, ...)
```

**Arguments**

`object` a fitted `pfr` object as produced by `pfr`

newdata	a named list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. All variables provided to newdata should be in the format supplied to <code>pfr</code> , i.e., functional predictors must be supplied as matrices with each row corresponding to one observed function. Index variables for the functional covariates are reused from the fitted model object or alternatively can be supplied as attributes of the matrix of functional predictor values. Any variables in the model not specified in newdata are set to their average values from the data supplied during fitting the model
type	character; see <code>predict.gam</code> for details
se.fit	logical; see <code>predict.gam</code> for details
terms	character see <code>predict.gam</code> for details
PredOutOfRange	logical; if this argument is true then any functional predictor values in newdata corresponding to pfr terms that are greater[less] than the maximum[minimum] of the domain of the marginal basis for the rows of the tensor product smooth are set to the maximum[minimum] of the domain. If this argument is false, attempting to predict a value of the functional predictor outside the range of this basis produces an error
...	additional arguments passed on to <code>predict.gam</code>

**Value**

If `type == "lpmatrix"`, the design matrix for the supplied covariate values in long format. If `se == TRUE`, a list with entries `fit` and `se.fit` containing fits and standard errors, respectively. If `type == "terms"` or `"iterms"` each of these lists is a list of matrices of the same dimension as the response for newdata containing the linear predictor and its se for each term

```
##### Octane data example #####
data(gasoline)
N <- length(gasoline$octane)
wavelengths = 2*450:850
nir = matrix(NA, 60,401)
test <- sample(60,20)
for (i in 1:60) nir[i,] = gasoline$NIR[i, ] # changes class from AsIs to matrix
y <- gasoline$octane
fit <- pfr(y~af(nir,argvals=wavelengths,k=c(6,6), m=list(c(2,2),c(2,2))),
          subset=(1:N)[-test])
preds <- predict(fit,newdata=list(nir=nir[test,]),type='response')
plot(preds,y[test])
abline(a=0,b=1)
```

---

`print.summary.pffr`      *Print method for summary of a pffr fit*

---

### Description

Pretty printing for a `summary.pffr`-object. See `print.summary.gam()` for details.

### Usage

```
## S3 method for class 'summary.pffr'
print(x, digits = max(3, getOption("digits") - 3),
      signif.stars = getOption("show.signif.stars"), ...)
```

### Arguments

<code>x</code>	a fitted <code>pffr</code> -object
<code>digits</code>	controls number of digits printed in output.
<code>signif.stars</code>	Should significance stars be printed alongside output?
<code>...</code>	not used

### Value

A `summary.pffr` object

### Author(s)

Fabian Scheipl, adapted from `print.summary.gam()` by Simon Wood, Henric Nilsson

---

`pwcv`      *Pointwise cross-validation for function-on-scalar regression*

---

### Description

Estimates prediction error for a function-on-scalar regression model by leave-one-function-out cross-validation (CV), at each of a specified set of points.

### Usage

```
pwcv(fdobj, Z, L = NULL, lambda, eval.pts = seq(min(fdobj$basis$range),
max(fdobj$basis$range), length.out = 201), scale = FALSE)
```

**Arguments**

<code>fdoj</code>	a functional data object (class <code>fd</code> ) giving the functional responses.
<code>Z</code>	the model matrix, whose columns represent scalar predictors.
<code>L</code>	a row vector or matrix of linear contrasts of the coefficient functions, to be restricted to equal zero.
<code>lambda</code>	smoothing parameter: either a nonnegative scalar or a vector, of length <code>ncol(Z)</code> , of nonnegative values.
<code>eval.pts</code>	argument values at which the CV score is to be evaluated.
<code>scale</code>	logical value or vector determining scaling of the matrix <code>Z</code> (see <a href="#">scale</a> , to which the value of this argument is passed).

**Details**

Integrating the pointwise CV estimate over the function domain yields the *cross-validated integrated squared error*, the standard overall model fit score returned by [lofocv](#).

It may be desirable to derive the value of `lambda` from an appropriate call to [fosr](#), as in the example below.

**Value**

A vector of the same length as `eval.pts` giving the CV scores.

qq.pffr

*QQ plots for pffr model residuals*

---

## Description

This is simply a wrapper for code `qq.gam()`.

## Usage

```

## S3 method for class 'pffr'
qq(object, rep = 0, level = 0.9, s.rep = 10,
    type = c("deviance", "pearson", "response"), pch = ".", r1.col = 2,
    rep.col = "gray80", ...)

```

## Arguments

object	a fitted <code>pffr</code> -object
rep	How many replicate datasets to generate to simulate quantiles of the residual distribution. 0 results in an efficient simulation free method for direct calculation, if this is possible for the object family.
level	If simulation is used for the quantiles, then reference intervals can be provided for the QQ-plot, this specifies the level. 0 or less for no intervals, 1 or more to simply plot the QQ plot for each replicate generated.

s.rep	how many times to randomize uniform quantiles to data under direct computation.
type	what sort of residuals should be plotted? See <a href="#">residuals.gam</a> .
pch	plot character to use. 19 is good.
rl.col	color for the reference line on the plot.
rep.col	color for reference bands or replicate reference plots.
...	extra graphics parameters to pass to plotting functions.

---

quadWeights	<i>Compute quadrature weights</i>
-------------	-----------------------------------

---

**Description**

Utility function for numerical integration.

**Usage**

```
quadWeights(argvals, method = "trapezoidal")
```

**Arguments**

argvals	function arguments.
method	quadrature method. Can be either trapedoidal or midpoint.

**Value**

a vector of quadrature weights for the points supplied in argvals.

**Author(s)**

Clara Happ, with modifications by Philip Reiss

---

re	<i>Random effects constructor for fgam</i>
----	--

---

**Description**

Sets up a random effect for the levels of x. Use the by-argument to request random slopes.

**Usage**

```
re(x, ...)
```

**Arguments**

`x` a grouping variable: must be a factor  
`...` further arguments handed over to `s`, see [random.effects](#)

**Details**

See [random.effects](#) in `mgecv`.

**See Also**

[random.effects](#)

refund-internal	<i>Internal functions for the refund package</i>
-----------------	--

---

**Description**

These functions are ordinarily not to be called by the user, but if you contact the package authors with any questions about them, we'll do our best to clarify matters.

---

residuals.pffr	<i>Obtain residuals and fitted values for a pffr models</i>
----------------	---

---

**Description**

See [predict.pffr](#) for alternative options to extract estimated values from a `pffr` object. "Fitted values" here refers to the estimated additive predictor values, these will not be on the scale of the response for models with link functions.

**Usage**

```
## S3 method for class 'pffr'
residuals(object, reformat = TRUE, ...)
```

```
## S3 method for class 'pffr'
fitted(object, reformat = TRUE, ...)
```

**Arguments**

`object` a fitted `pffr`-object  
`reformat` logical, defaults to `TRUE`. Should residuals be returned in `n x y` index matrix form (regular grid data) or, respectively, in the shape of the originally supplied `ydata` argument (sparse/irregular data), or, if `FALSE`, simply as a long vector as returned by `resid.gam()`?  
`...` other arguments, passed to [residuals.gam](#).

**Value**

A matrix or ydata-like data.frame or a vector of residuals / fitted values (see reformat-argument)

**Author(s)**

Fabian Scheipl

---

rlrt.pfr	<i>Likelihood Ratio Test and Restricted Likelihood Ratio Test for inference of functional predictors</i>
----------	--

---

**Description**

NOTE: this function is designed to work with pfr\_old() rather than pfr(). Given a pfr object of family="gaussian", tests whether the function is identically equal to its mean (constancy), or whether the functional predictor significantly improves the model (inclusion). Based on zero-variance-component work of Crainiceanu et al. (2004), Scheipl et al. (2008), and Swihart et al. (2012).

**Usage**

```
rlrt.pfr(pfr.obj = pfr.obj, test = NULL, ...)
```

**Arguments**

pfr.obj	an object returned by pfr_old()
test	"constancy" will test functional form of the coefficient function of the last function listed in funcs in pfr.obj against the null of a constant line: the average of the functional predictor. "inclusion" will test functional form of the coefficient function of the last function listed in funcs in pfr.obj against the null of 0: that is, whether the functional predictor should be included in the model.
...	additional arguments

**Details**

A Penalized Functional Regression of family="gaussian" can be represented as a linear mixed model dependent on variance components. Testing whether certain variance components and (potentially) fixed effect coefficients are 0 correspond to tests of constancy and inclusion of functional predictors.

For rlrt.pfr, Restricted Likelihood Ratio Test is preferred for the constancy test as under the special B-splines implementation of pfr for the coefficient function basis the test involves only the variance component. Therefore, the constancy test is best for pfr objects with method="REML"; if the method was something else, a warning is printed and the model refit with "REML" and a test is then conducted.

For rlrt.pfr, the Likelihood Ratio Test is preferred for the inclusion test as under the special B-splines implementation of pfr for the coefficient function basis the test involves both the variance component and a fixed effect coefficient in the linear mixed model representation. Therefore, the inclusion test is best for pfr objects with method="ML"; if the method was something else, a warning is printed and the model refit with "ML" and a test is then conducted.

**Value**

p.val	the p-value for the full model (alternative) against the null specified by the test
test.stat	the test statistic, see Scheipl et al. 2008 and Swihart et al 2012
ma	the alternative model as fit with mgcv::gam
m0	the null model as fit with mgcv::gam
m	the model containing only the parameters being tested as fit with mgcv::gam

sff

*Construct a smooth function-on-function regression term***Description**

Defines a term  $\int_{s_{lo,i}}^{s_{hi,i}} f(X_i(s), s, t) ds$  for inclusion in an `mgcv::gam`-formula (or `bam` or `gamm` or `gamm4::gamm`) as constructed by `pfpr`. Defaults to a cubic tensor product B-spline with marginal second differences penalties for  $f(X_i(s), s, t)$  and integration over the entire range  $[s_{lo,i}, s_{hi,i}] = [\min(s_i), \max(s_i)]$ . Can't deal with any missing  $X(s)$ , unequal lengths of  $X_i(s)$  not (yet?) possible. Unequal ranges for different  $X_i(s)$  should work.  $X_i(s)$  is assumed to be numeric.

`sff()` IS AN EXPERIMENTAL FEATURE AND NOT WELL TESTED YET – USE AT YOUR OWN RISK.

**Usage**

```

sff(X, yind, xind = seq(0, 1, l = ncol(X)), basistype = c("te", "t2",
"s"), integration = c("simpson", "trapezoidal"), L = NULL,
limits = NULL, splinepars = list(bs = "ps", m = c(2, 2, 2)))

```

**Arguments**

`X` an  $n$  by `ncol(xind)` matrix of function evaluations  $X_i(s_{i1}), \dots, X_i(s_{iS}); i = 1, \dots, n$ .

`yind` *DEPRECATED* matrix (or vector) of indices of evaluations of  $Y_i(t)$ ; i.e. matrix with rows  $(t_{i1}, \dots, t_{iT})$ ; no longer used.

xind	vector of indices of evaluations of $X_i(s)$ , i.e. $(s_1, \dots, s_S)$
basistype	defaults to "te", i.e. a tensor product spline to represent $f(X_i(s), t)$ . Alternatively, use "s" for bivariate basis functions (see <a href="#">s</a> ) or "t2" for an alternative parameterization of tensor product splines (see <a href="#">t2</a> ).
integration	method used for numerical integration. Defaults to "simpson"'s rule. Alternatively and for non-equidistant grids, "trapezoidal".
L	optional: an n by ncol(xind) giving the weights for the numerical integration over s.
limits	defaults to NULL for integration across the entire range of $X(s)$ , otherwise specifies the integration limits $s_{hi,i}, s_{lo,i}$ : either one of "s<t" or "s<=t" for $(s_{hi,i}, s_{lo,i}) = (0, t)$ or a function that takes s as the first and t as the second argument and returns TRUE for combinations of values (s, t) if s falls into the integration range for the given t. This is an experimental feature and not well tested yet; use at your own risk.
splinepars	optional arguments supplied to the basistype-term. Defaults to a cubic tensor product B-spline with marginal second differences, i.e. <code>list(bs="ps", m=c(2, 2, 2))</code> . See <a href="#">te</a> or <a href="#">s</a> for details

**Value**

a list containing

- call a "call" to [te](#) (or [s](#), [t2](#)) using the appropriately constructed covariate and weight matrices (see [linear.functional.terms](#))
- data a list containing the necessary covariate and weight matrices

**Author(s)**

Fabian Scheipl, based on Sonja Greven's trick for fitting functional responses.

---

smooth.construct.dt.smooth.spec

*Domain Transformation basis constructor*

---

**Description**

The dt basis allows for any of the standard mgcv (or user-defined) bases to be applied to a transformed version of the original terms. Smooths may be of any number of terms. Transformations are specified by supplying a function of any or all of the original terms. "by" variables are not transformed.

**Usage**

```
## S3 method for class 'dt.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

object	a smooth specification object, generated by <code>s()</code> , <code>te()</code> , <code>ti()</code> , or <code>t2()</code> , with <code>bs="dt"</code>
data	a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element.
knots	a list containing any knots supplied for basis setup - in same order and with same names as data. Can be NULL.

**Details**

object should be created with an `xt` argument. For non-tensor-product smooths, this will be a list with the following elements:

1. `tf` (required): a function or character string (or list of functions and/or character strings) defining the coordinate transformations; see further details below.
2. `bs` (optional): character string indicating the bs for the basis applied to the transformed coordinates; if empty, the appropriate defaults are used.
3. `basis` (optional): character string indicating type of bivariate basis used. Options include "s" (the default), "te", "ti", and "t2", which correspond to `s`, `te`, `ti`, and `t2`.
4. ... (optional): for tensor product smooths, additional arguments to the function specified by `basis` that are not available in `s()` can be included here, e.g. `d`, `np`, etc.

For tensor product smooths, we recommend using `s()` to set up the basis, and specifying the tensor product using `xt$basis` as described above. If the basis is set up using `te()`, then the variables in `object$term` will be split up, meaning all transformation functions would have to be univariate.

**Value**

An object of class "dt.smooth". This will contain all the elements associated with the `smooth.construct` object from the inner smooth (defined by `xt$bs`), in addition to an `xt` element used by the `Predict.matrix` method.

**Transformation Functions**

Let `nterms = length(object$term)`. The `tf` element can take one of the following forms:

1. a function of `nargs` arguments, where `nargs <= nterms`. If `nterms > 1`, it is assumed that this function will be applied to the first term of `object$term`. If all argument names of the function are term names, then those arguments will correspond to those terms; otherwise, they will correspond to the first `nargs` terms in `object$term`.
2. a character string corresponding to one of the built-in transformations (listed below).
3. A list of length `ntfuncs`, where `ntfuncs <= nterms`, containing either the functions or character strings described above. If this list is named with term names, then the transformation functions will be applied to those terms; otherwise, they will be applied to the first `ntfuncs` terms in `object$term`.

The following character strings are recognized as built-in transformations:

- "log": log transformation (univariate)
- "ecdf": empirical cumulative distribution function (univariate)
- "linear01": linearly rescale from 0 to 1 (univariate)
- "s-t": first term ("s") minus the second term ("t") (bivariate)
- "s/t": first term ("s") divided by the second term ("t") (bivariate)
- "QTransform": performs a time-specific ecdf transformation for a bivariate smooth, where time is indicated by the first term, and  $x$  by the second term. Primarily for use with `refund: :af`.

Some transformations rely on a fixed "pivot point" based on the data used to fit the model, e.g. quantiles (such as the min or max) of this data. When making predictions based on these transformations, the transformation function will need to know what the pivot points are, based on the original (not prediction) data. In order to accomplish this, we allow the user to specify that they want their transformation function to refer to the original data (as opposed to whatever the "current" data is). This is done by appending a zero ("0") to the argument name.

For example, suppose you want to scale the term linearly so that the data used to define the basis ranges from 0 to 1. The wrong way to define this transformation function: `function(x) {(x - min(x))/(max(x) - min(x))}`. This function will result in incorrect predictions if the range of data for which predictions are being made is not the same as the range of data that was used to define the basis. The proper way to define this function: `function(x) {(x - min(x0))/(max(x0) - min(x0))}`. By referring to `x0` instead of `x`, you are indicating that you want to use the original data instead of the current data. This may seem strange to refer to a variable that is not one of the arguments, but the "dt" constructor explicitly places these variables in the environment of the transformation function to make them available.

*Basis constructor for FPC terms*

---

### Description

Basis constructor for FPC terms

### Usage

```
## S3 method for class 'fpc.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

object	a fpc.smooth.spec object, usually generated by a term <code>s(x,bs="fpc")</code> ; see Details.
data	a list containing the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). Only the first element of this list is used.
knots	not used, but required by the generic <code>smooth.construct</code> .

**Details**

object must contain an `xt` element. This is a list that can contain the following elements:

**X** (required) matrix of functional predictors

**method** (required) the method of finding principal components; options include "svd" (unconstrained), "fpc.sc", "fpc.face", or "fpc.ssvd"

**npc** (optional) the number of PC's to retain

**pve** (only needed if npc not supplied) the percent variance explained used to determine npc

**penalize** (required) if FALSE, the smoothing parameter is set to 0

**bs** the basis class used to pre-smooth  $X$ ; default is "ps"

Any additional options for the pre-smoothing basis (e.g. `k`, `m`, etc.) can be supplied in the corresponding elements of object. See [s](#) for a full list of options.

**Value**

An object of class "fpc.smooth". In addition to the elements listed in [smooth.construct](#), the object will contain

sm	the smooth that is fit in order to generate the basis matrix over <code>object\$term</code>
V.A	the matrix of principal components

 smooth.construct.pco.smooth.spec

*Principal coordinate ridge regression*

---

### Description

Smooth constructor function for principal coordinate ridge regression fitted by `gam`. When the principal coordinates are defined by a relevant distance among functional predictors, this is a form of nonparametric scalar-on-function regression. Reiss et al. (2016) describe the approach and apply it to dynamic time warping distances among functional predictors.

### Usage

```
## S3 method for class 'pco.smooth.spec'
smooth.construct(object, data, knots)
```

### Arguments

object	a smooth specification object, usually generated by a term of the form <code>s(dummy, bs="pco", k, xt)</code> ; see Details.
data	a list containing just the data.
knots	IGNORED!

### Value

An object of class `pco.smooth`. The resulting object has an `xt` element which contains details of the multidimensional scaling, which may be interesting.

### Details

The constructor is not normally called directly, but is rather used internally by `gam`.

In a `gam` term of the above form `s(dummy, bs="pco", k, xt)`,

- `dummy` is an arbitrary vector (or name of a column in `data`) whose length is the number of observations. This is not actually used, but is required as part of the input to `s`. Note that if multiple `pco` terms are used in the model, there must be multiple unique term names (e.g., "dummy1", "dummy2", etc).
- `k` is the number of principal coordinates (e.g., `k=9` will give a 9-dimensional projection of the data).
- `xt` is a list supplying the distance information, in one of two ways. (i) A matrix `Dmat` of distances can be supplied directly via `xt=list(D=Dmat, ...)`. (ii) Alternatively, one can use `xt=list(realdata=..., dist_fn=..., ...)` to specify a data matrix `realdata` and distance function `dist_fn`, whereupon a distance matrix `dist_fn(realdata)` is created.

The list `xt` also has the following optional elements:

- add: Passed to `cmdscale` when performing multidimensional scaling; for details, see the help for that function. (Default FALSE.)
- fastcmd: if TRUE, multidimensional scaling is performed by `cmdscale_lanczos`, which uses Lanczos iteration to eigendecompose the distance matrix; if FALSE, MDS is carried out by `cmdscale`. Default is FALSE, to use `cmdscale`.

### Examples

```
## Not run:
# a simulated example
library(refund)
library(mgcv)
require(dtw)

## First generate the data
Xnl <- matrix(0, 30, 101)
set.seed(813)
tt <- sort(sample(1:90, 30))
for(i in 1:30){
  Xnl[i, tt[i]:(tt[i]+4)] <- -1
  Xnl[i, (tt[i]+5):(tt[i]+9)] <- 1
}
X.toy <- Xnl + matrix(rnorm(30*101, ,0.05), 30)
y.toy <- tt + rnorm(30, 0.05)
y.rainbow <- rainbow(30, end=0.9)[(y.toy-min(y.toy))/
  diff(range(y.toy))*29+1]

## Display the toy data
par(mfrow=c(2, 2))
matplot((0:100)/100, t(Xnl[c(4, 25), ]), type="l", xlab="t", ylab="",
  ylim=range(X.toy), main="Noiseless functions")
matplot((0:100)/100, t(X.toy[c(4, 25), ]), type="l", xlab="t", ylab="",
  ylim=range(X.toy), main="Observed functions")
matplot((0:100)/100, t(X.toy), type="l", lty=1, col=y.rainbow, xlab="t",
  ylab="", main="Rainbow plot")

## Obtain DTW distances
D.dtw <- dist(X.toy, method="dtw", window.type="sakoechiba", window.size=5)

## Compare PC vs. PCo ridge regression
```

```

# matrix to store results
GCVmat <- matrix(NA, 15, 2)
# dummy response variable
dummy <- rep(1,30)

# loop over possible projection dimensions
for (k. in 1:15){
  # fit PC (m1) and PCo (m2) ridge regression
  m1 <- gam(y.toy ~ s(dummy, bs="pco", k=k.,
    xt=list(realdata=X.toy, dist_fn=dist)), method="REML")
  m2 <- gam(y.toy ~ s(dummy, bs="pco", k=k., xt=list(D=D.dtw)), method="REML")
  # calculate and store GCV scores
  GCVmat[k., ] <- length(y.toy) * c(sum(m1$residuals^2)/m1$df.residual^2,
    sum(m2$residuals^2)/m2$df.residual^2)
}

## plot the GCV scores per dimension for each model
matplot(GCVmat, lty=1:2, col=1, pch=16:17, type="o", ylab="GCV",
  xlab="Number of principal components / coordinates",
  main="GCV score")
legend("right", c("PC ridge regression", "DTW-based PCoRR"), lty=1:2, pch=16:17)

## example of making a prediction

# fit a model to the toy data
m <- gam(y.toy ~ s(dummy, bs="pco", k=2, xt=list(D=D.dtw)), method="REML")

# first build the distance matrix
# in this case we just subsample the original matrix
# see ?pco_predict_preprocess for more information on formatting this data
dist_list <- list(dummy = as.matrix(D.dtw)[, c(1:5,10:15)])

# preprocess the prediction data
pred_data <- pco_predict_preprocess(m, newdata=NULL, dist_list)

# make the prediction
p <- predict(m, pred_data)

# check that these are the same as the corresponding fitted values
print(cbind(fitted(m)[ c(1:5,10:15)],p))

## End(Not run)

```

---

smooth.construct.pcre.smooth.spec

*mgcv-style constructor for PC-basis functional random effects*

---

**Description**

Sets up design matrix for functional random effects based on the PC scores of the covariance operator of the random effect process. See [smooth.construct.re.smooth.spec](#) for more details on mgcv-style smoother specification and [pcre](#) for the corresponding `pffr()`-formula wrapper.

**Usage**

```
## S3 method for class 'pcre.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

object	a smooth specification object, see <a href="#">smooth.construct</a>
data	see <a href="#">smooth.construct</a>
knots	see <a href="#">smooth.construct</a>

**Value**

An object of class "random.effect". See [smooth.construct](#) for the elements that this object will contain.

**Author(s)**

Fabian Scheipl; adapted from 're' constructor by S.N. Wood.

---

```
smooth.construct.peer.smooth.spec
Basis constructor for PEER terms
```

---

**Description**

Smooth basis constructor to define structured penalties (Randolph et al., 2012) for smooth terms.

**Usage**

```
## S3 method for class 'peer.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

object	a <code>peer.smooth.spec</code> object, usually generated by a term <code>s(x, bs="peer")</code> ; see <a href="#">Details</a> .
data	a list containing the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). Only the first element of this list is used.
knots	not used, but required by the generic <code>smooth.construct</code> .

## Details

The smooth specification object, defined using `s()`, should contain an `xt` element. `xt` will be a list that contains additional information needed to specify the penalty. The type of penalty is indicated by `xt$penstype`. There are four types of penalties available:

1. `xt$penstype=="RIDGE"` for a ridge penalty, the default
2. `xt$penstype=="D"` for a difference penalty. The order of the difference penalty is specified by the `m` argument of `s()`.
3. `xt$penstype=="DECOMP"` for a decomposition-based penalty,  $bP_Q + a(I - P_Q)$ , where  $P_Q = Q^t(QQ^t)^{-1}Q$ . The  $Q$  matrix must be specified by `xt$Q`, and the scalar  $a$  by `xt$phia`. The number of columns of  $Q$  must be equal to the length of the data. Each row represents a basis function where the functional predictor is expected to lie, according to prior belief.
4. `xt$penstype=="USER"` for a user-specified penalty matrix  $L$ , supplied by `xt$L`.

## Value

An object of class "peer.smooth". See [smooth.construct](#) for the elements that this object will contain.

[peer](#)

---

smooth.construct.pi.smooth.spec

*Parametric Interaction basis constructor*

---

## Description

The pi basis is appropriate for smooths of multiple variables. Its purpose is to parameterize the way in which the basis changes with one of those variables. For example, suppose the smooth is over three variables,  $x$ ,  $y$ , and  $t$ , and we want to parameterize the effect of  $t$ . Then the pi basis will assume  $f(x, y, t) = \sum_k g_k(t) * f_k(x, y)$ , where the  $g_k(t)$  functions are pre-specified and the  $f_k(x, y)$  functions are estimated using a bivariate basis. An example of a parametric interaction is a linear interaction, which would take the form  $f(x, y, t) = f_1(x, y) + t * f_2(x, y)$ .

**Usage**

```
## S3 method for class 'pi.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

object	a smooth specification object, generated by, e.g., <code>s(x, y, t, bs="pi", xt=list(g=list(g1, g2, g3)))</code> . For transformation functions <code>g1</code> , <code>g2</code> , and <code>g3</code> , see Details below.
data	a list containing the variables of the smooth ( <code>x</code> , <code>y</code> , and <code>t</code> above), as well as any by variable.
knots	a list containing any knots supplied for basis setup - in same order and with same names as <code>data</code> . Can be <code>NULL</code> .

**Details**

All functions  $f_k()$  are defined using the same basis set. Accordingly, they are penalized using a single block-diagonal penalty matrix and one smoothing parameter. Future versions of this function may be able to relax this assumption.

`object` should be defined (using `s()`) with an `xt` argument. This argument is a list that could contain any of the following elements:

1. `g`: the functions  $g_k(t)$ , specified as described below.
2. `bs`: the basis code used for the functions  $f_k()$ ; defaults to thin-plate regression splines, which is `mgcv`'s default. The same basis will be used for all  $k$ .
3. `idx`: an integer index indicating which variable from `object$term` is to be parameterized, i.e., the  $t$  variable; defaults to `length(object$term)`
4. `mp`: flag to indicate whether multiple penalties should be estimated, one for each  $f_k()$ . Defaults to `TRUE`. If `FALSE`, the penalties for each  $k$  are combined into a single block-diagonal penalty matrix (with one smoothing parameter).
5. `...`: further `xt` options to be passed onto the basis for  $f_k()$ .

`xt$g` can be entered in one of the following forms:

1. a list of functions of length  $k$ , where each function is of one argument (assumed to be  $t$ )
2. one of the following recognized character strings: `code="linear"`, indicating a linear interaction, i.e.  $f(x, t) = f_1(x) + t * f_2(x)$ ; `"quadratic"`, indicating a quadratic interaction, i.e.  $f(x, t) = f_1(x) + t * f_2(x) + t^2 * f_3(x)$ ; or `"none"`, indicating no interaction with  $t$ , i.e.  $f(x, t) = f_1(x)$ .

The only one of the above elements that is required is `xt`. If default values for `bs`, `idx`, and `mp` are desired, `xt` may also be entered as the `g` element itself; i.e. `xt=g`, where `g` is either the list of functions or an acceptable character string.

Additional arguments for the lower-dimensional basis over  $f_k$  may be entered using the corresponding arguments of `s()`, e.g. `k`, `m`, `sp`, etc. For example, `s(x, t, bs="pi", k=15, xt=list(g="linear", bs="ps"))` will define a linear interaction with `t` of a univariate `p`-spline basis of dimension 15 over `x`.

**Value**

An object of class `"pi.smooth"`. See `smooth.construct` for the elements it will contain.

**Author(s)**

Fabian Scheipl and Jonathan Gellar

---

smooth.construct.pss.smooth.spec

*P-spline constructor with modified 'shrinkage' penalty*

---

**Description**

Construct a B-spline basis with a modified difference penalty of full rank (i.e., that also penalizes low-order polynomials).

**Usage**

```
## S3 method for class 'pss.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

object	see <a href="#">smooth.construct</a> . The shrinkage factor can be specified via <code>object\$xt\$shrink</code>
data	see <a href="#">smooth.construct</a> .
knots	see <a href="#">smooth.construct</a> .

**Details**

This penalty-basis combination is useful to avoid non-identifiability issues for `ff` terms. See 'ts' or 'cs' in [smooth.terms](#) for similar "shrinkage penalties" for thin plate and cubic regression splines. The basic idea is to replace the  $k$ -th zero eigenvalue of the original penalty by  $s^k \nu_m$ , where  $s$  is the shrinkage factor (defaults to 0.1) and  $\nu_m$  is the smallest non-zero eigenvalue. See reference for the original idea, implementation follows that in the 'ts' and 'cs' constructors (see [smooth.terms](#)).

**Author(s)**

Fabian Scheipl; adapted from 'ts' and 'cs' constructors by S.N. Wood.

sofa

*SOFA (Sequential Organ Failure Assessment) Data***Description**

A dataset containing the SOFA scores (Vincent et al, 1996). for 520 patients, hospitalized in the intensive care unit (ICU) with Acute Lung Injury. Daily measurements are available for as long as each one remains in the ICU. This is an example of variable-domain functional data, as described by Gellar et al. (2014).

**Usage**

sofa

**Format**

A data frame with 520 rows (subjects) and 7 variables:

**death** binary indicator that the subject died in the ICU

**SOFA** 520 x 173 matrix in variable-domain format (a ragged array). Each column represents an ICU day. Each row contains the SOFA scores for a subject, one per day, for as long as the subject remained in the ICU. The remaining cells of each row are padded with NAs. SOFA scores range from 0 to 24, increasing with severity of organ failure. Missing values during one's ICU stay have been imputed using LOCF.

**SOFA\_raw** Identical to the SOFA element, except that it contains some missing values during one's hospitalization. These missing values arise when a subject leaves the ICU temporarily, only to be re-admitted. SOFA scores are not monitored outside the ICU.

**los** ICU length of stay, i.e., the number of days the patient remained in the ICU prior to death or final discharge.

**age** Patient age

**male** Binary indicator for male gender

**Charlson** Charlson co-morbidity index, a measure of baseline health status (before hospitalization and ALI).

**Details**

The data was collected as part of the Improving Care of ALI Patients (ICAP) study (Needham et al., 2006). If you use this dataset as an example in written work, please cite the study protocol.

summary.pffr

*Summary for a pffr fit*

---

### Description

Take a fitted pffr-object and produce summaries from it. See [summary.gam\(\)](#) for details.

### Usage

```
## S3 method for class 'pffr'
summary(object, ...)
```

### Arguments

object            a fitted pffr-object  
 ...                see [summary.gam\(\)](#) for options.

### Value

A list with summary information, see [summary.gam\(\)](#)

### Author(s)

Fabian Scheipl, adapted from [summary.gam\(\)](#) by Simon Wood, Henric Nilsson

---

summary.pfr

*Summary for a pfr fit*

---

### Description

Take a fitted pfr-object and produce summaries from it. See [summary.gam\(\)](#) for details.

### Usage

```
## S3 method for class 'pfr'
summary(object, ...)
```

**Arguments**

object            a fitted pfr-object  
 ...                see `summary.gam()` for options.

**Details**

This function currently simply strips the "pfr" class label and calls `summary.gam`.

**Value**

A list with summary information, see `summary.gam()`

---

 vb\_cs\_fPCA

---

*Cross-sectional FoSR using Variational Bayes and FPCA*

---

**Description**

Fitting function for function-on-scalar regression for cross-sectional data. This function estimates model parameters using a VB and estimates the residual covariance surface using FPCA.

**Usage**

```
vb_cs_fPCA(formula, data = NULL, verbose = TRUE, Kt = 5, Kp = 2,
  alpha = 0.1, Aw = NULL, Bw = NULL, Apsi = NULL, Bpsi = NULL,
  argvals = NULL)
```

**Arguments**

formula            a formula indicating the structure of the proposed model.  
 data                an optional data frame, list or environment containing the variables in the model. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which the function is called.  
 verbose            logical defaulting to TRUE – should updates on progress be printed?  
 Kt                 number of spline basis functions used to estimate coefficient functions  
 Kp                 number of FPCA basis functions to be estimated  
 alpha              tuning parameter balancing second-derivative penalty and zeroth-derivative penalty (alpha = 0 is all second-derivative penalty)  
 Aw                 hyperparameter for inverse gamma controlling variance of spline terms for population-level effects  
 Bw                 hyperparameter for inverse gamma controlling variance of spline terms for population-level effects

Apsi	hyperparameter for inverse gamma controlling variance of spline terms for FPC effects
Bpsi	hyperparameter for inverse gamma controlling variance of spline terms for FPC effects
argvals	not currently implemented

 vb\_cs\_wish

---

*Cross-sectional FoSR using Variational Bayes and Wishart prior*

---

**Description**

Fitting function for function-on-scalar regression for cross-sectional data. This function estimates model parameters using VB and estimates the residual covariance surface using a Wishart prior.

**Usage**

```
vb_cs_wish(formula, data = NULL, verbose = TRUE, Kt = 5,
  alpha = 0.1, min.iter = 10, max.iter = 50, Aw = NULL,
  Bw = NULL, v = NULL)
```

**Arguments**

formula	a formula indicating the structure of the proposed model.
data	an optional data frame, list or environment containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which the function is called.
verbose	logical defaulting to TRUE – should updates on progress be printed?
Kt	number of spline basis functions used to estimate coefficient functions
alpha	tuning parameter balancing second-derivative penalty and zeroth-derivative penalty (alpha = 0 is all second-derivative penalty)
min.iter	minimum number of iterations of VB algorithm
max.iter	maximum number of iterations of VB algorithm
Aw	hyperparameter for inverse gamma controlling variance of spline terms for population-level effects; if NULL, defaults to Kt/2.

Bw	hyperparameter for inverse gamma controlling variance of spline terms for population-level effects; if NULL, defaults to $1/2 \text{tr}(\mu.q.\text{beta})$ of the model
v	hyperparameter for inverse Wishart prior on residual covariance; if NULL, Psi defaults to an FPCA decomposition of the residual covariance in which residuals are estimated based on an OLS fit of the model (note the "nugget effect" on this covariance is assumed to be constant over the time domain).

 vis.fgam

---

*Visualization of FGAM objects*

---

**Description**

Produces perspective or contour plot views of an estimated surface corresponding to [af](#) terms fit using [fgam](#) or plots “slices” of the estimated surface or estimated second derivative surface with one of its arguments fixed and corresponding twice-standard error “Bayesian” confidence bands constructed using the method in Marra and Wood (2012). See the details.

**Usage**

```
vis.fgam(object, af.term, xval = NULL, tval = NULL, deriv2 = FALSE,
         theta = 50, plot.type = "persp", ticktype = "detailed", ...)
```

**Arguments**

object	an fgam object, produced by <a href="#">fgam</a>
af.term	character; the name of the functional predictor to be plotted. Only important if multiple af terms are fit. Defaults to the first af term in object\$call
xval	a number in the range of functional predictor to be plotted. The surface will be plotted with the first argument of the estimated surface fixed at this value
tval	a number in the domain of the functional predictor to be plotted. The surface will be plotted with the second argument of the estimated surface fixed at this value. Ignored if xval is specified
deriv2	logical; if TRUE, plot the estimated second derivative surface along with Bayesian confidence bands. Only implemented for the "slices" plot from either xval or tval being specified
theta	numeric; viewing angle; see <a href="#">persp</a>
plot.type	one of "contour" (to use <a href="#">levelplot</a> ) or "persp" (to use <a href="#">persp</a> ). Ignored if either xval or tval is specified
ticktype	how to draw the tick marks if plot.type="persp". Defaults to "detailed"
...	other options to be passed to <a href="#">persp</a> , <a href="#">levelplot</a> , or <a href="#">plot</a>

**Details**

The confidence bands used when plotting slices of the estimated surface or second derivative surface are the ones proposed in Marra and Wood (2012). These are a generalization of the "Bayesian" intervals of Wahba (1983) with an adjustment for the uncertainty about the model intercept. The estimated covariance matrix of the model parameters is obtained from assuming a particular Bayesian model on the parameters.

**Value**

Simply produces a plot

**Examples**

```
##### DTI Example #####
data(DTI)

## only consider first visit and cases (since no PASAT scores for controls)
y <- DTI$pasat[DTI$visit==1 & DTI$case==1]
X <- DTI$cca[DTI$visit==1 & DTI$case==1,]

## remove samples containing missing data
ind <- rowSums(is.na(X))>0

y <- y[!ind]
X <- X[!ind,]

## fit the fgam using FA measurements along corpus
## callosum as functional predictor with PASAT as response
## using 8 cubic B-splines for each marginal bases with
## third order marginal difference penalties
## specifying gamma>1 enforces more smoothing when using GCV
## to choose smoothing parameters
```

```

fit <- fgam(y~af(X,splinepars=list(k=c(8,8),m=list(c(2,3),c(2,3))))),gamma=1.2)

## contour plot of the fitted surface
vis.fgam(fit,plot.type='contour')

## similar to Figure 5 from McLean et al.
## Bands seem too conservative in some cases
xval <- runif(1, min(fit$fgam$ft[[1]]$Xrange), max(fit$fgam$ft[[1]]$Xrange))
tval <- runif(1, min(fit$fgam$ft[[1]]$xind), max(fit$fgam$ft[[1]]$xind))
par(mfrow=c(4, 1))
vis.fgam(fit, af.term='X', deriv2=FALSE, xval=xval)
vis.fgam(fit, af.term='X', deriv2=FALSE, tval=tval)
vis.fgam(fit, af.term='X', deriv2=TRUE, xval=xval)
vis.fgam(fit, af.term='X', deriv2=TRUE, tval=tval)

```

vis.pfr

*Visualization of PFR objects*

## Description

Produces perspective or contour plot views of an estimated surface corresponding smooths over two or more dimensions. Alternatively plots “slices” of the estimated surface or estimated second derivative surface with one of its arguments fixed. Corresponding twice-standard error “Bayesian” confidence bands are constructed using the method in Marra and Wood (2012). See the details.

## Usage

```

vis.pfr(object, select = 1, xval = NULL, tval = NULL,
        deriv2 = FALSE, theta = 50, plot.type = "persp",
        ticktype = "detailed", ...)

```

## Arguments

object	an pfr object, produced by <a href="#">pfr</a>
select	index for the smooth term to be plotted, according to its position in the model formula (and in object\$smooth). Not needed if only one multivariate term is present.
xval	a number in the range of functional predictor to be plotted. The surface will be plotted with the first argument of the estimated surface fixed at this value
tval	a number in the domain of the functional predictor to be plotted. The surface will be plotted with the second argument of the estimated surface fixed at this value. Ignored if xval is specified.
deriv2	logical; if TRUE, plot the estimated second derivative surface along with Bayesian confidence bands. Only implemented for the "slices" plot from either xval or tval being specified
theta	numeric; viewing angle; see <a href="#">persp</a>

plot.type        one of "contour" (to use [levelplot](#)) or "persp" (to use [persp](#)). Ignored if either xval or tval is specified

ticktype        how to draw the tick marks if plot.type="persp". Defaults to "detailed"

...              other options to be passed to [persp](#), [levelplot](#), or [plot](#)

### Details

The confidence bands used when plotting slices of the estimated surface or second derivative surface are the ones proposed in Marra and Wood (2012). These are a generalization of the "Bayesian" intervals of Wahba (1983) with an adjustment for the uncertainty about the model intercept. The estimated covariance matrix of the model parameters is obtained from assuming a particular Bayesian model on the parameters.

### Value

vis.pfr(fit, deriv2=FALSE, tval=tval)
vis.pfr(fit, deriv2=TRUE, xval=xval)
vis.pfr(fit, deriv2=TRUE, tval=tval)

```

---

Xt\_siginv\_X

*Internal computation function*

---

### Description

Internal function used compute the products  $(X \text{ otimes } \Theta)^t (I \text{ otimes } \Sigma^{-1}) (X \text{ otimes } \Theta)$  and  $(X \text{ otimes } \Theta)^t (I \text{ otimes } \Sigma^{-1}) (y)$  in cross-sectional VB algorithm and Gibbs sampler

### Usage

```
Xt_siginv_X(tx, siginv, y = NULL)
```

### Arguments

tx	transpose of the X design matrix
siginv	inverse variance matrix
y	outcome matrix. if NULL, function computes first product; if not, function computes second product.
