# Package 'seqHMM'

October 22, 2019

**Title** Mixture Hidden Markov Models for Social Sequence Data and Other Multivariate, Multichannel Categorical Time Series

**Version** 1.0.14 **Date** 2019-10-21

Description Designed for fitting hidden (latent) Markov models and mixture hidden Markov models for social sequence data and other categorical time series. Also some more restricted versions of these type of models are available: Markov models, mixture Markov models, and latent class models. The package supports models for one or multiple subjects with one or multiple parallel sequences (channels). External covariates can be added to explain cluster membership in mixture models. The package provides functions for evaluating and comparing models, as well as functions for visualizing of multichannel sequence data and hidden Markov models. Models are estimated using maximum likelihood via the EM algorithm and/or direct numerical maximization with analytical gradients. All main algorithms are written in C++ with support for parallel computation. Documentation is available via several vignettes in this page, and the paper by Helske and Helske (2019, <doi:10.18637/jss.v088.i03>).

biofam3c	Three-channel biofam data	

# **Description**

Biofam data from the TraMineR package converted into three channels.

#### **Format**

A list including three sequence data sets for 2000 individuals with 16 state variables, and a separate data frame with 1 id variable, 8 covariates, and 2 weights variables.

#### **Details**

This data is constructed from the biofam data in the TraMineR package. Here the original state sequences are converted into three separate data sets: children, married, and left. These include the corresponding life states from age 15 to 30: childless or (having) children; single, married, or divorced; and (living) with parents or left home.

Note that the divorced state does not give information on parenthood or residence, so a guess is made based on preceeding states.

The fourth data frame covariates is a collection of additional variables from the original data:

```
idhous
            id
sex
            sex
birthyr
            birth year
            first nationality
nat_1_02
plingu02
            language of questionnaire
p02r01
            religion
            religious participation
p02r04
cspfaj
            father's social status
            mother's social status
cspmoj
wp00tbgp
            weights inflating to the Swiss population
wp00tbgs
            weights respecting sample size
```

The data is loaded by calling data(biofam3c). It was built using following code:

```
data("biofam" , package = "TraMineR")
biofam3c <- with(biofam, {

## Building one channel per type of event left, children or married
bf <- as.matrix(biofam[, 10:25])
children <- bf == 4 | bf == 5 | bf == 6
married <- bf == 2 | bf == 3 | bf == 6
left <- bf == 1 | bf == 3 | bf == 5 | bf == 7</pre>
```

```
children[children == TRUE] <- "children"</pre>
children[children == FALSE] <- "childless"</pre>
# Divorced parents
div \leftarrow bf[(rowSums(bf == 7) > 0 \& rowSums(bf == 5) > 0)]
             (rowSums(bf == 7) > 0 & rowSums(bf == 6) > 0),]
children[rownames(bf)
married[married == TRUE] <- "married"</pre>
married[married == FALSE] <- "single"</pre>
married[bf == 7] <- "divorced"</pre>
left[left == TRUE] <- "left home"</pre>
left[left == FALSE] <- "with parents"</pre>
# Divorced living with parents (before divorce)
wp \leftarrow bf[(rowSums(bf == 7) > 0 \& rowSums(bf == 2) > 0 \&
           rowSums(bf == 3) == 0 & rowSums(bf == 5) == 0 &
          rowSums(bf == 6) == 0) |
         (rowSums(bf == 7) > 0 & rowSums(bf == 4) > 0 &
          rowSums(bf == 3) == 0 & rowSums(bf == 5) == 0 &
          rowSums(bf == 6) == 0), ]
left[rownames(bf)
list("children" = children, "married" = married, "left" = left,
  "covariates" = biofam[, c(1:9, 26:27)])
})
```

build\_hmm

Build a Hidden Markov Model

## **Description**

Function build\_hmm constructs a hidden Markov model object of class hmm.

#### Usage

```
build_hmm(observations, n_states, transition_probs, emission_probs,
initial_probs, state_names = NULL, channel_names = NULL, ...)
```

#### **Arguments**

observations An stslist object (see segdef) containing the sequences, or a list of such

objects (one for each channel).

n\_states A scalar giving the number of hidden states (not used if starting values for model

parameters are given with initial\_probs, transition\_probs, or emission\_probs).

transition\_probs

A matrix of transition probabilities.

emission\_probs A matrix of emission probabilities or a list of such objects (one for each chan-

nel). Emission probabilities should follow the ordering of the alphabet of obser-

vations (alphabet(observations), returned as symbol\_names).

initial\_probs A vector of initial state probabilities.

state\_names A list of optional labels for the hidden states. If NULL, the state names are taken

from the row names of the transition matrix. If this is also NULL, numbered states

are used.

channel\_names A vector of optional names for the channels.

... Additional arguments to simulate\_transition\_probs.

#### **Details**

The returned model contains some attributes such as nobs and df, which define the number of observations in the model and the number of estimable model parameters, used in computing BIC. When computing nobs for a multichannel model with C channels, each observed value in a single channel amounts to 1/C observation, i.e. a fully observed time point for a single sequence amounts to one observation. For the degrees of freedom df, zero probabilities of the initial model are defined as structural zeroes.

#### Value

Object of class hmm with the following elements:

observations State sequence object or a list of such objects containing the data.

transition\_probs A matrix of transition probabilities.

emission\_probs A matrix or a list of matrices of emission probabilities.

initial\_probs A vector of initial probabilities.

state\_names Names for hidden states.

symbol\_names Names for observed states.

channel\_names Names for channels of sequence data.

length\_of\_sequences (Maximum) length of sequences.

n\_sequences Number of sequences.

n\_symbols Number of observed states (in each channel).

n\_states Number of hidden states.

n\_channels Number of channels.

build\_lcm

Build a Latent Class Model

# **Description**

Function build\_1cm is a shortcut for constructing a latent class model as a restricted case of an mhmm object.

# Usage

```
build_lcm(observations, n_clusters, emission_probs, formula, data,
  coefficients, cluster_names = NULL, channel_names = NULL)
```

# Arguments

observations An stslist object (see seqdef) containing the sequences, or a list of such

objects (one for each channel).

n\_clusters A scalar giving the number of clusters/submodels (not used if starting values for

model parameters are given with emission\_probs).

emission\_probs A matrix containing emission probabilities for each class by rows, or in case

of multichannel data a list of such matrices. Note that the matrices must have dimensions  $k \times s$  where k is the number of latent classes and s is the number of unique symbols (observed states) in the data. Emission probabilities should follow the ordering of the alphabet of observations (alphabet(observations),

returned as symbol\_names).

formula Covariates as an object of class formula, left side omitted.

data An optional data frame, list or environment containing the variables in the model.

If not found in data, the variables are taken from environment(formula).

coefficients An optional kxl matrix of regression coefficients for time-constant covariates

for mixture probabilities, where l is the number of clusters and k is the number of covariates. A logit-link is used for mixture probabilities. The first column is

set to zero.

cluster\_names A vector of optional names for the classes/clusters.

channel\_names A vector of optional names for the channels.

build\_lcm 9

#### Value

```
Object of class mhmm with the following elements:
observations State sequence object or a list of such containing the data.
transition_probs A matrix of transition probabilities.
emission_probs A matrix or a list of matrices of emission probabilities.
initial_probs A vector of initial probabilities.
coefficients A matrix of parameter coefficients for covariates (covariates in rows, clusters in
    columns).
X Covariate values for each subject.
cluster names Names for clusters.
state_names Names for hidden states.
symbol_names Names for observed states.
channel_names Names for channels of sequence data
length_of_sequences (Maximum) length of sequences.
n_sequences Number of sequences.
n_symbols Number of observed states (in each channel).
n_states Number of hidden states.
n_channels Number of channels.
n_covariates Number of covariates.
n_clusters Number of clusters.
```

build\_mhmm

Build a Mixture Hidden Markov Model

# **Description**

Function build\_mhmm constructs a mixture hidden Markov model object of class mhmm.

#### Usage

```
build_mhmm(observations, n_states, transition_probs, emission_probs,
  initial_probs, formula, data, coefficients, cluster_names = NULL,
  state_names = NULL, channel_names = NULL, ...)
```

# **Arguments**

observations An stslist object (see seqdef) containing the sequences, or a list of such

objects (one for each channel).

n\_states A numerical vector giving the number of hidden states in each submodel (not

used if starting values for model parameters are given with initial\_probs,

transition\_probs, or emission\_probs).

transition\_probs

A list of matrices of transition probabilities for the submodel of each cluster.

r

emission\_probs A list which contains matrices of emission probabilities or a list of such objects (one for each channel) for the submodel of each cluster. Note that the matrices must have dimensions mxs where m is the number of hidden states and s is the number of unique symbols (observed states) in the data. Emission probabilities should follow the ordering of the alphabet of observations

(alphabet(observations), returned as symbol\_names).

initial\_probs A list which contains vectors of initial state probabilities for the submodel of

each cluster.

formula Covariates as an object of class formula, left side omitted.

data An optional data frame, list or environment containing the variables in the model.

If not found in data, the variables are taken from environment(formula).

coefficients An optional kxl matrix of regression coefficients for time-constant covariates

for mixture probabilities, where l is the number of clusters and k is the number of covariates. A logit-link is used for mixture probabilities. The first column is

set to zero.

cluster\_names A vector of optional names for the clusters.

state\_names A list of optional labels for the hidden states. If NULL, the state names are taken

as row names of transition matrices. If this is also NULL, numbered states are

used.

channel\_names A vector of optional names for the channels.

... Additional arguments to simulate\_transition\_probs.

#### **Details**

The returned model contains some attributes such as nobs and df, which define the number of observations in the model and the number of estimable model parameters, used in computing BIC. When computing nobs for a multichannel model with C channels, each observed value in a single channel amounts to 1/C observation, i.e. a fully observed time point for a single sequence amounts to one observation. For the degrees of freedom df, zero probabilities of the initial model are defined as structural zeroes.

#### Value

Object of class mhmm with following elements:

observations State sequence object or a list of such containing the data.

transition\_probs A matrix of transition probabilities.

emission\_probs A matrix or a list of matrices of emission probabilities.

initial\_probs A vector of initial probabilities.

coefficients A matrix of parameter coefficients for covariates (covariates in rows, clusters in columns).

X Covariate values for each subject.

cluster\_names Names for clusters.

state\_names Names for hidden states.

symbol\_names Names for observed states.

channel\_names Names for channels of sequence data

length\_of\_sequences (Maximum) length of sequences.

n\_sequences Number of sequences.

n\_symbols Number of observed states (in each channel).

n\_states Number of hidden states.

n\_channels Number of channels.

n\_covariates Number of covariates.

n\_clusters Number of clusters.

```

# **Description**

Function build\_mm builds and automatically estimates a Markov model. It is also a shortcut for constructing a Markov model as a restricted case of an hmm object.

# Usage

```
build_mm(observations)
```

# **Arguments**

```
observations An stslist object (see seqdef) containing the sequences.
```

# **Details**

Unlike the other build functions in seqHMM, the build\_mm function automatically estimates the model parameters. As initial and transition probabilities can be directly estimated from the observed initial state probabilities and transition counts, there is no need for starting values or further estimation with the fit\_model function.

#### Value

Object of class hmm with following elements:

observations State sequence object or a list of such containing the data.

transition\_probs A matrix of transition probabilities.

emission\_probs A matrix or a list of matrices of emission probabilities.

initial\_probs A vector of initial probabilities.

state\_names Names for hidden states.

symbol\_names Names for observed states.

channel\_names Names for channels of sequence data.

length\_of\_sequences (Maximum) length of sequences.

n\_sequences Number of sequences.

n\_symbols Number of observed states (in each channel).

n\_states Number of hidden states.

n\_channels Number of channels.

# See Also

```
plot.hmm for plotting the model.
```

# **Examples**

```
# Construct sequence data
data("mvad", package = "TraMineR")

mvad_alphabet <-
    c("employment", "FE", "HE", "joblessness", "school", "training")
mvad_labels <- c("employment", "further education", "higher education",
    "joblessness", "school", "training")
mvad_scodes <- c("EM", "FE", "HE", "JL", "SC", "TR")
mvad_seq <- seqdef(mvad, 17:86, alphabet = mvad_alphabet,
    states = mvad_scodes, labels = mvad_labels, xtstep = 6)

# Define a color palette for the sequence data
attr(mvad_seq, "cpal") <- colorpalette[[6]]

# Estimate the Markov model
mm_mvad <- build_mm(observations = mvad_seq)</pre>
```

build\_mmm

Build a Mixture Markov Model

# **Description**

Function build\_mmm is a shortcut for constructing a mixture Markov model as a restricted case of an mhmm object.

# Usage

```
build_mmm(observations, n_clusters, transition_probs, initial_probs,
  formula, data, coefficients, cluster_names = NULL, ...)
```

# **Arguments**

observations An stslist object (see seqdef) containing the sequences.

n\_clusters A scalar giving the number of clusters/submodels (not used if starting values for

model parameters are given with initial\_probs and transition\_probs).

transition\_probs

A list of matrices of transition probabilities for submodels of each cluster.

initial\_probs A list which contains vectors of initial state probabilities for submodels of each

cluster.

formula Covariates as an object of class formula, left side omitted.

data An optional data frame, list or environment containing the variables in the model.

If not found in data, the variables are taken from environment(formula).

coefficients An optional kxl matrix of regression coefficients for time-constant covariates

for mixture probabilities, where l is the number of clusters and k is the number of covariates. A logit-link is used for mixture probabilities. The first column is

set to zero.

cluster\_names A vector of optional names for the clusters.

... Additional arguments to simulate\_transition\_probs.

#### Value

Object of class mhmm with following elements:

observations State sequence object or a list of such containing the data.

transition\_probs A matrix of transition probabilities.

emission\_probs A matrix or a list of matrices of emission probabilities.

initial\_probs A vector of initial probabilities.

coefficients A matrix of parameter coefficients for covariates (covariates in rows, clusters in columns).

X Covariate values for each subject.

cluster\_names Names for clusters.

state\_names Names for hidden states.

symbol\_names Names for observed states.

channel\_names Names for channels of sequence data

length\_of\_sequences (Maximum) length of sequences.

n\_sequences Number of sequences.

n\_symbols Number of observed states (in each channel).

n\_states Number of hidden states.

n\_channels Number of channels.

n\_covariates Number of covariates.

n\_clusters Number of clusters.

# Color palette with 9 colors
colorpalette[[9]]
# Color palette with 24 colors
colorpalette[[24]]
```

estimate\_coef

Estimate Regression Coefficients of Mixture Hidden Markov Models

# **Description**

Function estimate\_coef estimates the regression coefficients of mixture hidden Markov models and its restricted variants while keeping other parameters fixed.

# Usage

```
estimate_coef(model, threads = 1)
```

#### **Arguments**

model An object of class hmm or mhmm.

Number of threads to use in parallel computing. The default is 1. threads

fit\_model Estimate Parameters of (Mixture) Hidden Markov Models and Their Restricted Variants

**Description** 

Function fit\_model estimates the parameters of mixture hidden Markov models and its restricted variants using maximimum likelihood. Initial values for estimation are taken from the corresponding components of the model with preservation of original zero probabilities.

# Usage

```
fit_model(model, em_step = TRUE, global_step = FALSE,
  local_step = FALSE, control_em = list(), control_global = list(),
  control_local = list(), lb, ub, threads = 1, log_space = FALSE,
  ...)
```

# **Arguments**

An object of class hmm or mhmm. model Logical. Whether or not to use the EM algorithm at the start of the parameter em\_step estimation. The default is TRUE. Logical. Whether or not to use global optimization via nloptr (possibly after global\_step the EM step). The default is FALSE. local\_step Logical. Whether or not to use local optimization via nloptr (possibly after the EM and/or global steps). The default is FALSE. Optional list of control parameters for the EM algorithm. Possible arguments control\_em

maxeval The maximum number of iterations, the default is 1000. Note that iteration counter starts with -1 so with maxeval=1 you get already two iterations. This is for backward compatibility reasons.

**print\_level** The level of printing. Possible values are 0 (prints nothing), 1 (prints information at the start and the end of the algorithm), 2 (prints at every iteration), and for mixture models 3 (print also during optimization of coefficients).

**reltol** Relative tolerance for convergence defined as  $(logLik_new-logLik_old)/(abs(logLik_old)+$ 0.1). The default is 1e-10.

restart A list containing options for possible EM restarts with the following components:

**times** Number of restarts of the EM algorithm using random initial values. The default is 0, i.e. no restarts.

transition Logical. Should the original transition probabilities be varied? The default is TRUE.

**emission** Logical. Should the original emission probabilities be varied? The default is TRUE.

sd Standard deviation for rnorm used in randomization. The default is 0.25.

maxeval Maximum number of iterations, the default is control\_em\$maxeval print\_level Level of printing in restarted EM steps. The default is control\_em\$print\_level.

**reltol** Relative tolerance for convergence at restarted EM steps. The default is control\_em\$reltol. If the relative change of the final model of the restart phase is larger than the tolerance for the original EM phase, the final model is re-estimated with the original reltol and maxeval at the end of the EM step.

**n\_optimum** Save the log-likelihood values of the n\_optimum best models (from all estimated models including the the first EM run.). The default is min(times + 1, 25).

**use\_original** If TRUE. Use the initial values of the input model as starting points for the permutations. Otherwise permute the results of the first EM run.

control\_global Optional list of additional arguments for nloptr argument opts. The default values are

algorithm "NLOPT\_GD\_MLSL\_LDS"

local\_opts list(algorithm = "NLOPT\_LD\_LBFGS", ftol\_rel = 1e-6, xtol\_rel = 1e-4)

maxeval 10000 (maximum number of iterations in global optimization algorithm.)

**maxtime** 60 (maximum time for global optimization. Set to 0 for unlimited time.)

control\_local Optional list of additional arguments for nloptr argument opts. The default

values are

algorithm "NLOPT\_LD\_LBFGS"

ftol\_rel 1e-10 xtol rel 1e-8

maxeval 10000 (maximum number of iterations)

1b, ub Lower and upper bounds for parameters in Softmax parameterization. The de-

fault interval is [pmin(-25, 2\*initialvalues), pmax(25, 2\*initialvalues)], except for gamma coefficients, where the scale of covariates is taken into account. Note that it might still be a good idea to scale covariates around unit

scale. Bounds are used only in the global optimization step.

threads Number of threads to use in parallel computing. The default is 1.

log\_space Make computations using log-space instead of scaling for greater numerical sta-

bility at a cost of decreased computational performance. The default is FALSE.

... Additional arguments to nloptr.

#### **Details**

The fitting function provides three estimation steps: 1) EM algorithm, 2) global optimization, and 3) local optimization. The user can call for one method or any combination of these steps, but should note that they are preformed in the above-mentioned order. The results from a former step are used as starting values in a latter, except for some of global optimization algorithms (such as MLSL and StoGO) which only use initial values for setting up the boundaries for the optimization.

It is possible to rerun the EM algorithm automatically using random starting values based on the first run of EM. Number of restarts is defined by the restart argument in control\_em. As the EM algorithm is relatively fast, this method might be preferred option compared to the proper global optimization strategy of step 2.

The default global optimization method (triggered via global\_step = TRUE) is the multilevel single-linkage method (MLSL) with the LDS modification (NLOPT\_GD\_MLSL\_LDS as algorithm in control\_global), with L-BFGS as the local optimizer. The MLSL method draws random starting points and performs a local optimization from each. The LDS modification uses low-discrepancy sequences instead of pseudo-random numbers as starting points and should improve the convergence rate. In order to reduce the computation time spent on non-global optima, the convergence tolerance of the local

optimizer is set relatively large. At step 3, a local optimization (L-BFGS by default) is run with a lower tolerance to find the optimum with high precision.

There are some theoretical guarantees that the MLSL method used as the default optimizer in step 2 shoud find all local optima in a finite number of local optimizations. Of course, it might not always succeed in a reasonable time. The EM algorithm can help in finding good boundaries for the search, especially with good starting values, but in some cases it can mislead. A good strategy is to try a couple of different fitting options with different combinations of the methods: e.g. all steps, only global and local steps, and a few evaluations of EM followed by global and local optimization.

By default, the estimation time is limited to 60 seconds in global optimization step, so it is advisable to change the default settings for the proper global optimization.

Any algorithm available in the nloptr function can be used for the global and local steps.

#### Value

logLik Log-likelihood of the estimated model.

**em\_results** Results after the EM step: log-likelihood (logLik), number of iterations (iterations), relative change in log-likelihoods between the last two iterations (change), and the log-likelihoods of the n\_optimum best models after the EM step (best\_opt\_restart).

**global\_results** Results after the global step.

**local\_results** Results after the local step.

**call** The matched function call.

forward\_backward

Forward and Backward Probabilities for Hidden Markov Model

# Description

The forward\_backward function computes scaled forward and backward probabilities of a hidden Markov model.

#### Usage

```
forward_backward(model, forward_only = FALSE, log_space = FALSE,
    threads = 1)
```

# **Arguments**

model Object of class hmm or mhmm.

forward\_only If TRUE, only forward probabilities are computed. The default is FALSE.

log\_space Compute forward and backward probabilities in logarithmic scale instead of

scaling. The default is FALSE.

threads Number of threads used in parallel computing. The default is 1.

30 gridplot

#### Value

List with components

forward\_probs If log\_space = FALSE, scaled forward probabilities, i.e. probability of state

given observations up to that time point. If log\_space = TRUE, logarithms of

non-scaled forward probabilities.

backward\_probs Scaled backward probabilities (log\_space = FALSE), or logarithms of non-scaled

backward probabilities(log\_space = TRUE).

scaling\_factors

Sum of non-scaled forward probabilities at each time point. Only computed if log\_space = FALSE.

In case of multiple observations, these are computed independently for each sequence.

# **Examples**

```
# Load a pre-defined MHMM
data("mhmm_biofam")

# Compute forward and backward probabilities
fb <- forward_backward(mhmm_biofam)

# The most probable hidden state at time t
# given the observations up to time t for the first subject:
apply(fb$forward_probs[, , 1], 2, which.max)</pre>
```

gridplot

Plot Multidimensional Sequence Plots in a Grid

# Description

Function gridplot plots multiple ssp objects to a grid.

# Usage

```
gridplot(x, nrow = NA, ncol = NA, byrow = FALSE,
  with.legend = "auto", legend.pos = "auto", legend.pos2 = "center",
  title.legend = "auto", ncol.legend = "auto",
  with.missing.legend = "auto", row.prop = "auto", col.prop = "auto",
  cex.legend = 1)
```

# **Arguments**

x A list of ssp objects.

nrow, ncol Optional arguments to arrange plots.

byrow Controls the order of plotting. Defaults to FALSE, i.e. plots are arranged column-

wise.

gridplot 31

with.legend	Defines if and how the legends for the states are plotted. The default value "auto" (equivalent to TRUE and "many") creates separate legends for each requested plot. Other possibilities are "combined" (all legends combined) and FALSE (no legend).			
legend.pos	Defines the positions of the legend boxes relative to the whole plot. Either one of "bottom" (equivalent to "auto") or "right", or a numerical vector of grid cells (by order) to print the legends to (the cells must be in one row/column).			
legend.pos2	Defines the positions of the legend boxes relative to the cell(s). One of "bottomright", "bottom", "bottomleft", "left", "topleft", "top" (the default), "topright", "right" and "center".			
title.legend	The titles for the legend boxes. The default "auto" takes the titles from the channel labels provided by the first object in x. NA prints no title.			
ncol.legend	(A vector of) the number of columns for the legend(s). The default "auto" creates one column for each legend.			
with.missing.legend				
	If set to "auto" (the default), a legend for the missing state is added automatically if one or more of the sequences in data contain missing states. With the value TRUE a legend for the missing state is added in any case; equivalently FALSE omits the legend for the missing state.			
row.prop	Sets the proportions of the row heights of the grid. The default value is "auto" for even row heights. Takes a vector of values from 0 to 1, with values summing to 1.			
col.prop	Sets the proportion of the column heights of the grid. The default value is "auto" for even column widths. Takes a vector of values from 0 to 1, with values summing to 1.			
cex.legend	Expansion factor for setting the size of the font for the labels in the legend. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.			

#### See Also

ssp for defining the plot before using gridplot, and plot.ssp for plotting only one ssp object.

## End(Not run)
```

hidden\_paths

Most Probable Paths of Hidden States

# **Description**

Function hidden\_paths computes the most probable path of hidden states of a (mixture) hidden Markov model given the observed sequences.

# Usage

```
hidden_paths(model)
```

# **Arguments**

model

A hidden Markov model of class hmm or a mixture HMM of class mhmm.

# Value

The most probable paths of hidden states as an stslist object (see seqdef). The log-probability is included as an attribute log\_prob.

# See Also

hmm\_biofam for information on the model used in the example; and seqIplot, ssplot, or mssplot for plotting hidden paths.

# **Examples**

```
# Load a pre-defined HMM
data("hmm_biofam")

# Compute the most probable hidden state paths given the data and the model
mpp <- hidden_paths(hmm_biofam)

# Plot hidden paths for the first 100 individuals
ssplot(mpp, type = "I", tlim = 1:100)

# Because the model structure is so sparse that the posterior probabilities are
# mostly peaked to single state at each time point, the joint probability of
# observations and most probable paths of hidden states is almost identical to
# log-likelihood:

sum(attr(mpp, "log_prob"))
logLik(hmm_biofam)</pre>
```

34 hmm\_biofam

hmm\_biofam

Hidden Markov model for the biofam data

# **Description**

A five-state hidden Markov model (HMM) fitted for the biofam data.

#### **Format**

A hidden Markov model of class hmm; a left-to-right model with four hidden states.

# **Details**

The model is loaded by calling data(hmm\_biofam). It was created with the following code:

```
data("biofam3c")
# Building sequence objects
marr_seq <- seqdef(biofam3c$married, start = 15,</pre>
  alphabet = c("single", "married", "divorced"))
child_seq <- seqdef(biofam3c$children, start = 15,</pre>
  alphabet = c("childless", "children"))
left_seq <- seqdef(biofam3c$left, start = 15,</pre>
  alphabet = c("with parents", "left home"))

hmm\_mvad

Hidden Markov model for the mvad data

# Description

A hidden Markov model (MMM) fitted for the mvad data.

36 hmm\_mvad

#### **Format**

A hidden Markov model of class hmm; unrestricted model with six hidden states.

#### **Details**

Model was created with the following code:

```
data("mvad", package = "TraMineR")
mvad_alphabet <-</pre>
  c("employment", "FE", "HE", "joblessness", "school", "training")
mvad_labels <- c("employment", "further education", "higher education",</pre>
  "joblessness", "school", "training")
mvad_scodes <- c("EM", "FE", "HE", "JL", "SC", "TR")</pre>
mvad_seq <- seqdef(mvad, 17:86, alphabet = mvad_alphabet,</pre>
  states = mvad_scodes, labels = mvad_labels, xtstep = 6)
attr(mvad_seq, "cpal") <- colorpalette[[6]]</pre>
# Starting values for the emission matrix
emiss <- matrix(</pre>

```

logLik.hmm

Log-likelihood of the Hidden Markov Model

# Description

Function logLik.hmm computes the log-likelihood value of a hidden Markov model.

# Usage

```
## S3 method for class 'hmm'
logLik(object, partials = FALSE, threads = 1,
   log_space = FALSE, ...)
```

# Arguments

object	A hidden Markov model of class hmm.
partials	Return a vector containing the individual contributions of each sequence to the total log-likelihood. The default is FALSE, which returns the sum of all log-likelihood components.
threads	Number of threads to use in parallel computing. The default is 1.
log_space	Make computations using log-space instead of scaling for greater numerical stability at the cost of decreased computational performance. The default is TRUE.
	Ignored.

# Value

Log-likelihood of the hidden Markov model. This is an object of class logLik with attributes nobs and df inherited from the model object.

### See Also

build\_hmm and fit\_model for building and fitting Hidden Markov models.

38 mc\_to\_sc

logLik.mhmm	Log-likelihood of the Mixture Hidden Markov Model	

# Description

Function logLik.mhmm computes the log-likelihood value of a mixture hidden Markov model.

# Usage

```
## S3 method for class 'mhmm'
logLik(object, partials = FALSE, threads = 1,
  log_space = FALSE, ...)
```

# **Arguments**

object	A mixture hidden Markov model of class mhmm.
partials	Return a vector containing the individual contributions of each sequence to the total log-likelihood. The default is FALSE, which returns the sum of all log-likelihood components.
threads	Number of threads to use in parallel computing. The default is 1.
log_space	Make computations using log-space instead of scaling for greater numerical stability at the cost of decreased computational performance. The default is TRUE.
	Ignored.

# Value

Log-likelihood of the mixture hidden Markov model. This is an object of class logLik with attributes nobs and df inherited from the model object.

# See Also

build\_mhmm and fit\_model for building and fitting mixture Hidden Markov models.

mc_to_sc	Transform a Multichannel Hidden Markov Model into a Single Channel Representation

# **Description**

Transforms data and parameters of a multichannel model into a single channel model. Observed states (symbols) are combined and parameters multiplied across channels.

# Usage

```
mc_to_sc(model, combine_missing = TRUE, all_combinations = FALSE)
```

mc\_to\_sc\_data 39

# **Arguments**

model

An object of class hmm or mhmm.

combine\_missing

Controls whether combined states of observations at time t are coded missing (coded with \* in stslists) if one or more of the channels include missing information at time t. Defaults to TRUE. FALSE keeps missing states as they are, producing more states in data; e.g. single/childless/\* where the observation in channel 3 is missing.

all\_combinations

Controls whether all possible combinations of observed states are included in the single channel representation or only combinations that are found in the data. Defaults to FALSE, i.e. only actual observations are included.

### **Details**

Note that in case of no missing observations, the log-likelihood of the original and transformed models are identical but the AIC and BIC can be different as the model attribute df is recomputed based on the single channel representation.

#### See Also

build\_hmm and fit\_model for building and fitting Hidden Markov models; and hmm\_biofam for information on the model used in the example.

# **Examples**

```
# Loading a hidden Markov model of the biofam data (hmm object)
data("hmm_biofam")

# Convert the multichannel model to a single-channel model
sc <- mc_to_sc(hmm_biofam)

# Likelihoods of the single-channel and the multichannel model are the same
# (Might not be true if there are missing observations)
logLik(sc)
logLik(hmm_biofam)</pre>
```

mc\_to\_sc\_data

Merge Multiple Sequence Objects into One (from Multichannel to Single Channel Data)

# **Description**

Function mc\_to\_sc\_data combines observed states of multiple sequence objects into one, time point by time point.

40 mc\_to\_sc\_data

### Usage

```
mc_to_sc_data(data, combine_missing = TRUE, all_combinations = FALSE)
```

# **Arguments**

data A list of state sequence objects (stslists) created with the seqdef function. combine\_missing

Controls whether combined states of observations at time t are coded missing (coded with \* in stslists) if one or more of the channels include missing information at time t. Defaults to TRUE. FALSE keeps missing states as they are, producing more states in data; e.g. single/childless/\* where the observation in channel 3 is missing.

all\_combinations

Controls whether all possible combinations of observed states are included in the single channel representation or only combinations that are found in the data. Defaults to FALSE, i.e. only actual observations are included.

### See Also

mc\_to\_sc for transforming multichannel hmm or mhmm objects into single-channel representations; ssplot for plotting multiple sequence data sets in the same plot; and seqdef for creating state sequence objects.

### **Examples**

```
# Load three-channel sequence data
data("biofam3c")

mhmm\_biofam

Mixture hidden Markov model for the biofam data

# **Description**

A mixture hidden Markov model (MHMM) fitted for the biofam data.

#### **Format**

A mixture hidden Markov model of class mhmm: three clusters with left-to-right models including 4, 4, and 6 hidden states. Two covariates, sex and cohort, explaining the cluster membership.

### **Details**

The model was created with the following code:

```
data("biofam3c")

## Building sequence objects
marr_seq <- seqdef(biofam3c$married, start = 15,
    alphabet = c("single", "married", "divorced"))
child_seq <- seqdef(biofam3c$children, start = 15,
    alphabet = c("childless", "children"))
left_seq <- seqdef(biofam3c$left, start = 15,
    alphabet = c("with parents", "left home"))

## Choosing colors
attr(marr_seq, "cpal") <- c("#AB82FF", "#E6AB02", "#E7298A")
attr(child_seq, "cpal") <- c("#A6CEE3", "#FC8D62")
attr(left_seq, "cpal") <- c("#A6CEE3", "#E31A1C")

## Starting values for emission probabilities
# Cluster 1
B1_marr <- matrix(</pre>
```

42 mhmm\_biofam

```
c(0.8, 0.1, 0.1, # High probability for single
    0.8, 0.1, 0.1,
    0.3, 0.6, 0.1, # High probability for married

mhmm\_mvad

Mixture hidden Markov model for the mvad data

# **Description**

A mixture hidden Markov model (MHMM) fitted for the mvad data.

# **Format**

A mixture hidden Markov model of class mhmm: two clusters including 3 and 4 hidden states. No covariates.

mhmm\_mvad 45

### **Details**

The model is loaded by calling data(mhmm\_mvad). It was created with the following code:

```
data("mvad", package = "TraMineR")
mvad_alphabet <-</pre>
  c("employment", "FE", "HE", "joblessness", "school", "training")
mvad_labels <- c("employment", "further education", "higher education",</pre>
  "joblessness", "school", "training")
mvad_scodes <- c("EM", "FE", "HE", "JL", "SC", "TR")</pre>
mvad_seq <- seqdef(mvad, 17:86, alphabet = mvad_alphabet,</pre>
  states = mvad_scodes, labels = mvad_labels, xtstep = 6)
attr(mvad_seq, "cpal") <- colorpalette[[6]]</pre>
# Starting values for the emission matrices

mssplot

Interactive Stacked Plots of Multichannel Sequences and/or Most Probable Paths for Mixture Hidden Markov Models

# **Description**

Function mssplot plots stacked sequence plots of observation sequences and/or most probable hidden state paths for each model of the mhmm object (model chosen according to the most probable path).

# Usage

```
mssplot(x, ask = FALSE, which.plots = NULL, hidden.paths = NULL,
    plots = "obs", type = "d", tlim = 0, sortv = NULL,
    sort.channel = 1, dist.method = "OM", with.missing = FALSE,
    missing.color = NULL, title = NA, title.n = TRUE, cex.title = 1,
    title.pos = 1, with.legend = "auto", ncol.legend = "auto",
    with.missing.legend = "auto", legend.prop = 0.3, cex.legend = 1,
    hidden.states.colors = "auto", hidden.states.labels = "auto",
    xaxis = TRUE, xlab = NA, xtlab = NULL, xlab.pos = 1,
    ylab = "auto", hidden.states.title = "Hidden states",
    yaxis = FALSE, ylab.pos = "auto", cex.lab = 1, cex.axis = 1, ...)
```

### **Arguments**

Mixture hidden Markov model object of class mhmm. Х ask If TRUE and which.plots is NULL, plot.mhmm operates in interactive mode, via menu. Defaults to FALSE. which.plots The number(s) of the requested model(s) as an integer vector. The default NULL produces all plots. hidden.paths Output from the hidden\_paths function. The default value NULL computes hidden paths automatically, if needed. plots What to plot. One of "obs" for observations (the default), "hidden.paths" for most probable paths of hidden states, or "both" for observations and hidden paths together. The type of the plot. Available types are "I" for index plots and "d" for state type distribution plots (the default). See segplot for details. tlim Indexes of the subjects to be plotted (the default is 0, i.e. all subjects are plotted). For example, tlim = 1:10 plots the first ten subjects in data. A sorting variable or a sort method (one of "from. start", "from. end", "mds.obs", sortv or "mds.hidden") for type = "I". The value "mds.hidden" is only available when which = "both" and which = "hidden.paths". Options "mds.obs" and "mds.hidden" automatically arrange the sequences according to the scores of multidimensional scaling (using cmdscale) for the observed data or hidden states paths. MDS scores are computed from distances/dissimilarities using a metric defined in argument dist.method. See plot.stslist for more details on "from.start" and "from.end". The number of the channel according to which the "from. start" or "from. end" sort.channel sorting is done. Sorting according to hidden states is called with value 0. The default value is 1 (the first channel). dist.method The metric to be used for computing the distances of the sequences if multidimensional scaling is used for sorting. One of "OM" (optimal matching, the default), "LCP" (longest common prefix), "RLCP" (reversed LCP, i.e. longest common suffix), "LCS" (longest common subsequence), "HAM" (Hamming distance), and "DHD" (dynamic Hamming distance). Transition rates are used for defining substitution costs if needed. See segdef for more information on Controls whether missing states are included in state distribution plots (type = with.missing "d"). The default is FALSE. missing.color Alternative color for representing missing values in the sequences. By default, this color is taken from the missing.color attribute of the sequence object. title A vector of main titles for the graphics. The default is NA: if title.n = TRUE, the name of the cluster and the number of subjects is plotted. FALSE prints no titles, even when title.n = TRUE. title.n Controls whether the number of subjects is printed in the main titles of the plots. The default is TRUE: n is plotted if title is anything but FALSE. cex.title Expansion factor for setting the size of the font for the main titles. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.

title.pos Controls the position of the main titles of the plots. The default value is 1. Values greater than 1 will place the title higher.

with.legend Defines if and where the legend for the states is plotted. The default value

"auto" (equivalent to TRUE and "right") creates separate legends for each requested plot and positiones them on the right-hand side of the plot. Other possible values are "bottom", "right.combined", and "bottom.combined", of which the last two create a combined legend in the selected position. FALSE

prints no legend.

ncol.legend (A vector of) the number of columns for the legend(s). The default "auto" creates one column for each legend.

with.missing.legend

If set to "auto" (the default), a legend for the missing state is added automatically if one or more of the sequences in the data/channel contains missing states and type = "I". If type = "d" missing states are omitted from the legends unless with.missing = TRUE. With the value TRUE a legend for the missing state is added in any case; equivalently FALSE omits the legend for the missing state.

legend.prop Sets the proportion of the graphic area used for plotting the legend when with.legend

is not FALSE. The default value is 0.3. Takes values from 0 to 1.

cex.legend Expansion factor for setting the size of the font for the labels in the legend. The default value is 1. Values lesser than 1 will reduce the size of the font, values

greater than 1 will increase the size.

hidden.states.colors

A vector of colors assigned to hidden states. The default value "auto" uses the colors assigned to the stslist object (created with seqdef) if hidden.paths is given; otherwise colors from colorpalette are automatically used.

hidden.states.labels

Labels for the hidden states. The default value "auto" uses the names provided in x\$state\_names if x is an hmm object; otherwise the number of the hidden state.

xaxis Controls whether an x-axis is plotted below the plot at the bottom. The default value is TRUE.

xlab An optional label for the x-axis. If set to NA, no label is drawn.

xtlab Optional labels for the x-axis tick labels. If unspecified, the column names of

the sequence object are used (see seqdef).

xlab.pos Controls the position of the x-axis label. The default value is 1. Values greater

than 1 will place the label further away from the plot.

ylab Labels for the channels shown as labels for y-axes. A vector of names for each

channel (observations). The default value "auto" uses the names provided in x-channel\_names if x is an hmm object; otherwise the names of the list in x if given, or the number of the channel if names are not given. FALSE prints no

labels.

hidden.states.title

Optional label for the hidden state plot (in the y-axis). The default is "Hidden

states".

yaxis Controls whether or not to plot the y-axis. The default is FALSE.

ylab.pos	Controls the position of the y axis labels (labels for channels and/or hidden states). Either "auto" or a numerical vector indicating how far away from the plots the titles are positioned. The default value "auto" positions all titles on line 1. Shorter vectors are recycled.
cex.lab	Expansion factor for setting the size of the font for the axis labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
cex.axis	Expansion factor for setting the size of the font for the x-axis tick labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
	Other arguments to be passed on to seqplot.

    # Interactive plot
    mssplot(mhmm_biofam)
}
```

plot.hmm

Plot hidden Markov models

# **Description**

Function plot. hmm plots a directed graph with pie charts of emission probabilities as vertices/nodes.

# Usage

```
## S3 method for class 'hmm'
plot(x, layout = "horizontal", pie = TRUE,
  vertex.size = 40, vertex.label = "initial.probs",
  vertex.label.dist = "auto", vertex.label.pos = "bottom",
  vertex.label.family = "sans", loops = FALSE, edge.curved = TRUE,
```

```
edge.label = "auto", edge.width = "auto", cex.edge.width = 1,
edge.arrow.size = 1.5, edge.label.family = "sans",
label.signif = 2, label.scientific = FALSE, label.max.length = 6,
trim = 1e-15, combine.slices = 0.05,
combined.slice.color = "white", combined.slice.label = "others",
with.legend = "bottom", ltext = NULL, legend.prop = 0.5,
cex.legend = 1, ncol.legend = "auto", cpal = "auto",
cpal.legend = "auto", legend.order = TRUE, main = NULL, withlegend,
...)
```

#### **Arguments**

Х

A hidden Markov model object of class hmm created with build\_hmm (or build\_mm). Multichannel hmm objects are automatically transformed into single-channel objects. See function mc\_to\_sc for more information on the transformation.

layout

specifies the layout of vertices (nodes). Accepts a numerical matrix, a layout\_function (without quotation marks), or either of the predefined options "horizontal" (the default) and "vertical". Options "horizontal" and "vertical" position vertices at the same horizontal or vertical line. A two-column numerical matrix can be used to give x and y coordinates of the vertices. The layout\_functions available in the igraph package offer other automatic layouts for graphs.

pie

Are vertices plotted as pie charts of emission probabilities? Defaults to TRUE.

vertex.size

Size of vertices, given as a scalar or numerical vector. The default value is 40.

vertex.label

Labels for vertices. Possible options include "initial.probs", "names", NA, and a character or numerical vector. The default "initial.probs" prints the initial probabilities of the model and "names" prints the names of the hidden states as labels. NA prints no labels.

vertex.label.dist

Distance of the label of the vertex from its center. The default value "auto" places the label outside the vertex.

vertex.label.pos

Positions of vertex labels, relative to the center of the vertex. A scalar or numerical vector giving position(s) as radians or one of "bottom" (pi/2 as radians), "top" (-pi/2), "left" (pi), or "right" (0).

vertex.label.family, edge.label.family

Font family to be used for vertex/edge labels. See argument family in par for more information.

loops

Defines whether transitions back to same states are plotted.

edge.curved

Defines whether to plot curved edges (arcs, arrows) between vertices. A logical or numerical vector or scalar. Numerical values specify curvatures of edges. The default value TRUE gives curvature of 0.5 to all edges. See igraph.plotting for more information.

edge.label

Labels for edges. Possible options include "auto", NA, and a character or numerical vector. The default "auto" prints transition probabilities as edge labels. NA prints no labels.

Width(s) for edges. The default "auto" determines widths according to tranedge.width sition probabilities between hidden states. Other possibilities are a scalar or a numerical vector of widths. cex.edge.width An expansion factor for edge widths. Defaults to 1. edge.arrow.size Size of the arrow in edges (constant). Defaults to 1.5. Rounds labels of model parameters to specified number of significant digits, 2 label.signif by default. Ignored for user-given labels. label.scientific Defines if scientific notation should be used to describe small numbers. Defaults to FALSE, e.g. 0.0001 instead of 1e-04. Ignored for user-given labels. label.max.length Maximum number of digits in labels of model parameters. Ignored for usergiven labels. trim Scalar between 0 and 1 giving the highest probability of transitions that are plotted as edges, defaults to 1e-15. combine.slices Scalar between 0 and 1 giving the highest probability of emission probabilities that are combined into one state. The dafault value is 0.05. combined.slice.color Color of the combined slice that includes the smallest emission probabilities (only if argument "combine.slices" is greater than 0). The default color is white. combined.slice.label The label for combined states (when argument "combine.slices" is greater than 0) to appear in the legend. with.legend Defines if and where the legend of state colors is plotted. Possible values include "bottom" (the default), "top", "left", and "right". FALSE omits the legend. ltext Optional description of (combined) observed states to appear in the legend. A vector of character strings. See segplot for more information. legend.prop Proportion used for plotting the legend. A scalar between 0 and 1, defaults to 0.5. Expansion factor for setting the size of the font for labels in the legend. The cex.legend default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size. The number of columns for the legend. The default value "auto" sets the numncol.legend ber of columns automatically. Optional color palette for (combinations of) observed states. The default value cpal "auto" uses automatic color palette. Otherwise a vector of length x\$n\_symbols is given, i.e. the argument requires a color specified for all (combinations of) observed states even if they are not plotted (if the probability is less than combine.slices). cpal.legend Optional color palette for the legend, only considered when legend.order is FALSE. Should match ltext.

Whether to use the default order in the legend, i.e., order by appearance (first by

hidden state, then by emission probability). TRUE by default.

legend.order

```
main Main title for the plot. Omitted by default.
withlegend Deprecated. Use with.legend instead.
... Other parameters passed on to plot.igraph such as vertex.color, vertex.label.cex, or edge.lty.
```

  cex.legend = 1, ncol.legend = "auto", cpal = "auto",
  main = "auto", withlegend, ...)
```

# **Arguments**

x A hidden Markov model object of class mhmm created with build\_mhmm (or

build\_mmm or build\_lcm). Multichannel mhmm objects are automatically transformed into single-channel objects. See function mc\_to\_sc for more informa-

tion on the transformation.

interactive Whether to plot each cluster in succession or in a grid. Defaults to TRUE, i.e.

clusters are plotted one after another.

ask If TRUE and which.plots is NULL, plot.mhmm operates in interactive mode,

via menu. Defaults to FALSE. Ignored if interactive = FALSE.

which.plots The number(s) of the requested cluster(s) as an integer vector. The default NULL

produces all plots.

nrow, ncol Optional arguments to arrange plots in a grid. Ignored if interactive = TRUE.

byrow Controls the order of plotting in a grid. Defaults to FALSE, i.e. plots are arranged

column-wise. Ignored if interactive = TRUE.

row.prop Sets the proportions of the row heights of the grid. The default value is "auto"

for even row heights. Takes a vector of values from 0 to 1, with values summing

to 1. Ignored if interactive = TRUE.

col.prop Sets the proportion of the column heights of the grid. The default value is

"auto" for even column widths. Takes a vector of values from 0 to 1, with

values summing to 1. Ignored if interactive = TRUE.

layout specifies the layout of vertices (nodes). Accepts a numerical matrix, a layout\_

function (without quotation marks), or either of the predefined options "horizontal" (the default) and "vertical". Options "horizontal" and "vertical" position vertices at the same horizontal or vertical line. A two-column numerical matrix can be used to give x and y coordinates of the vertices. The layout\_functions available in the igraph package offer other automatic layouts for

graphs.

pie Are vertices plotted as pie charts of emission probabilities? Defaults to TRUE.

vertex.size Size of vertices, given as a scalar or numerical vector. The default value is 40.

vertex.label Labels for vertices. Possible options include "initial.probs", "names", NA,

and a character or numerical vector. The default "initial.probs" prints the initial probabilities of the model and "names" prints the names of the hidden

states as labels. NA prints no labels.

vertex.label.dist

Distance of the label of the vertex from its center. The default value "auto"

places the label outside the vertex.

vertex.label.pos

Positions of vertex labels, relative to the center of the vertex. A scalar or numerical vector giving position(s) as radians or one of "bottom" (pi/2 as radians),

"top" (-pi/2), "left" (pi), or "right" (0).

vertex.label.family, edge.label.family

Font family to be used for vertex/edge labels. See argument family in par for

more information.

loops Defines whether transitions back to same states are plotted.

edge.curved Defines whether to plot curved edges (arcs, arrows) between vertices. A logical or numerical vector or scalar. Numerical values specify curvatures of edges. The default value TRUE gives curvature of 0.5 to all edges. See igraph.plotting for more information. edge.label Labels for edges. Possible options include "auto", NA, and a character or numerical vector. The default "auto" prints transition probabilities as edge labels. NA prints no labels. Width(s) for edges. The default "auto" determines widths according to tranedge.width sition probabilities between hidden states. Other possibilities are a scalar or a numerical vector of widths. cex.edge.width An expansion factor for edge widths. Defaults to 1. edge.arrow.size Size of the arrow in edges (constant). Defaults to 1.5. label.signif Rounds labels of model parameters to specified number of significant digits, 2 by default. Ignored for user-given labels. label.scientific Defines if scientific notation should be used to describe small numbers. Defaults to FALSE, e.g. 0.0001 instead of 1e-04. Ignored for user-given labels. label.max.length Maximum number of digits in labels of model parameters. Ignored for usergiven labels. trim Scalar between 0 and 1 giving the highest probability of transitions that are plotted as edges, defaults to 1e-15. combine.slices Scalar between 0 and 1 giving the highest probability of emission probabilities that are combined into one state. The dafault value is 0.05. combined.slice.color Color of the combined slice that includes the smallest emission probabilities (only if argument "combine.slices" is greater than 0). The default color is white. combined.slice.label The label for combined states (when argument "combine.slices" is greater than 0) to appear in the legend. with.legend Defines if and where the legend of state colors is plotted. Possible values include "bottom" (the default), "top", "left", and "right". FALSE omits the legend. ltext Optional description of (combined) observed states to appear in the legend. A vector of character strings. See segplot for more information. Proportion used for plotting the legend. A scalar between 0 and 1, defaults to legend.prop 0.5. cex.legend Expansion factor for setting the size of the font for labels in the legend. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size. ncol.legend The number of columns for the legend. The default value "auto" sets the num-

ber of columns automatically.

cpal	Optional color palette for (combinations of) observed states. The default value "auto" uses automatic color palette. Otherwise a vector of length x\$n_symbols is given, i.e. the argument requires a color specified for all (combinations of) observed states even if they are not plotted (if the probability is less than combine.slices).
main	Optional main titles for plots. The default "auto" uses cluster_names as titles, NULL prints no titles.
withlegend	Deprecated. Use with.legend instead.
• • •	Other parameters passed on to plot.igraph such as vertex.color, vertex.label.cex, or edge.lty.

plot_colors(1:7)
plot_colors(c("yellow", "orange", "red", "purple", "blue", "green"))
plot_colors(rainbow(15))
```

posterior\_probs

Posterior Probabilities for (Mixture) Hidden Markov Models

# **Description**

Function posterior\_probs computes the posterior probabilities of hidden states of a (mixture) hidden Markov model.

# Usage

```
posterior_probs(model, log_space = FALSE)
```

60 print.hmm

# **Arguments**

model A (mixture) hidden Markov model of class hmm or mhmm.

log\_space Compute posterior probabilities in logarithmic scale. The default is FALSE.

# Value

Posterior probabilities. In case of multiple observations, these are computed independently for each sequence.

# **Examples**

```
# Load a pre-defined MHMM
data("mhmm_biofam")

# Compute posterior probabilities
pb <- posterior_probs(mhmm_biofam)

# Locally most probable states for the first subject:
pb[, , 1]</pre>
```

print.hmm

Print Method for a Hidden Markov Model

# **Description**

Prints the parameters of a (mixture) hidden Markov model.

# Usage

```
## S3 method for class 'hmm'
print(x, digits = 3, ...)
## S3 method for class 'mhmm'
print(x, digits = 3, ...)
## S3 method for class 'summary.mhmm'
print(x, digits = 3, ...)
```

# **Arguments**

x Hidden Markov model of class hmm or mhmm.digits Minimum number of significant digits to print.... Further arguments to print.default.

# See Also

build\_hmm and fit\_model for building and fitting hidden Markov models.

separate\_mhmm 61

separate_mhmm	Reorganize a mixture hidden Markov model to a list of separate hidden Markov models (covariates ignored)

# **Description**

The separate\_mhmm function reorganizes the parameters of a mhmm object into a list where each list component is an object of class hmm consisting of the parameters of the corresponding cluster.

# Usage

```
separate_mhmm(model)
```

### **Arguments**

model

Mixture hidden Markov model of class mhmm.

### Value

List with components of class hmm.

#### See Also

build\_mhmm and fit\_model for building and fitting MHMMs; and mhmm\_biofam for more information on the model used in examples.

# **Examples**

```
# Loading mixture hidden Markov model (mhmm object)
# of the biofam data
data("mhmm_biofam")

# Separate models for clusters
sep_hmm <- separate_mhmm(mhmm_biofam)

# Plotting the model for the first cluster
plot(sep_hmm[[1]])</pre>
```

seqdef

Imported Functions from TraMineR

# Description

Imported functions for convinience. For details, see the corresponding help pages of seqstatf, alphabet and seqdef.

62 seqHMM-deprecated

seqHMM

The seqHMM package

### **Description**

The seqHMM package is designed for fitting hidden (or latent) Markov models (HMMs) and mixture hidden Markov models (MHMMs) for social sequence data and other categorical time series. The package supports models for one or multiple subjects with one or multiple interdependent sequences (channels). External covariates can be added to explain cluster membership in mixture models. The package provides functions for evaluating and comparing models, as well as functions for easy plotting of multichannel sequences and hidden Markov models. Common restricted versions of (M)HMMs are also supported, namely Markov models, mixture Markov models, and latent class models.

### **Details**

Maximum likelihood estimation via the EM algorithm and direct numerical maximization with analytical gradients is supported. All main algorithms are written in C++. Parallel computation is implemented via OpenMP.

### References

Helske S. and Helske J. (2019). Mixture Hidden Markov Models for Sequence Data: The seqHMM Package in R, Journal of Statistical Software, 88(3), 1-32. doi:10.18637/jss.v088.i03

seqHMM-deprecated

Deprecated function(s) in the seqHMM package

# **Description**

These functions are provided for compatibility with older version of the seqHMM package. They will be eventually completely removed.

# Usage

```
fit_hmm(model, em_step = TRUE, global_step = FALSE,
  local_step = FALSE, control_em = list(), control_global = list(),
  control_local = list(), lb, ub, threads = 1, log_space = FALSE,
  ...)

fit_mhmm(model, em_step = TRUE, global_step = FALSE,
  local_step = FALSE, control_em = list(), control_global = list(),
  control_local = list(), lb, ub, threads = 1, log_space = FALSE,
  ...)

trim_hmm(model, maxit = 0, return_loglik = FALSE, zerotol = 1e-08,
  verbose = TRUE, ...)
```

seqHMM-deprecated 63

### **Arguments**

model An object of class hmm or mhmm.

em\_step Logical. Whether or not to use the EM algorithm at the start of the parameter estimation. The default is TRUE.

global\_step Logical. Whether or not to use global optimization via nloptr (possibly after the EM step). The default is FALSE.

local\_step Logical. Whether or not to use local optimization via nloptr (possibly after the EM and/or global steps). The default is FALSE.

control\_em Optional list of control parameters for the EM algorithm. Possible arguments are

**maxeval** The maximum number of iterations, the default is 1000. Note that iteration counter starts with -1 so with maxeval=1 you get already two iterations. This is for backward compatibility reasons.

**print\_level** The level of printing. Possible values are 0 (prints nothing), 1 (prints information at the start and the end of the algorithm), 2 (prints at every iteration), and for mixture models 3 (print also during optimization of coefficients).

**reltol** Relative tolerance for convergence defined as  $(logLik_new-logLik_old)/(abs(logLik_old)+0.1)$ . The default is 1e-10.

**restart** A list containing options for possible EM restarts with the following components:

**times** Number of restarts of the EM algorithm using random initial values. The default is 0, i.e. no restarts.

**transition** Logical. Should the original transition probabilities be varied? The default is TRUE.

**emission** Logical. Should the original emission probabilities be varied? The default is TRUE.

**sd** Standard deviation for rnorm used in randomization. The default is 0.25.

maxeval Maximum number of iterations, the default is control\_em\$maxeval

**print\_level** Level of printing in restarted EM steps. The default is control\_em\$print\_level.

reltol Relative tolerance for convergence at restarted EM steps. The default is control\_em\$reltol. If the relative change of the final model of the restart phase is larger than the tolerance for the original EM phase, the final model is re-estimated with the original reltol and maxeval at the end of the EM step.

n\_optimum Save the log-likelihood values of the n\_optimum best models
 (from all estimated models including the first EM run.). The default
 is min(times + 1,25).

**use\_original** If TRUE. Use the initial values of the input model as starting points for the permutations. Otherwise permute the results of the first EM run.

control\_global Optional list of additional arguments for nloptr argument opts. The default values are

simulate\_hmm

	<pre>algorithm "NLOPT_GD_MLSL_LDS" local_opts list(algorithm = "NLOPT_LD_LBFGS", ftol_rel = 1e-6, xtol_rel</pre>
control_local	Optional list of additional arguments for nloptr argument opts. The default values are
	algorithm "NLOPT_LD_LBFGS"
	ftol_rel 1e-10
	xtol_rel 1e-8
	maxeval 10000 (maximum number of iterations)
lb	Lower and upper bounds for parameters in Softmax parameterization. The default interval is $[pmin(-25, 2*initialvalues), pmax(25, 2*initialvalues)]$ , except for gamma coefficients, where the scale of covariates is taken into account. Note that it might still be a good idea to scale covariates around unit scale. Bounds are used only in the global optimization step.
ub	Lower and upper bounds for parameters in Softmax parameterization. The default interval is $[pmin(-25, 2*initialvalues), pmax(25, 2*initialvalues)]$ , except for gamma coefficients, where the scale of covariates is taken into account. Note that it might still be a good idea to scale covariates around unit scale. Bounds are used only in the global optimization step.
threads	Number of threads to use in parallel computing. The default is 1.
log_space	Make computations using log-space instead of scaling for greater numerical stability at a cost of decreased computational performance. The default is FALSE.
	Additional arguments to nloptr.
maxit	Number of iterations. After zeroing small values, the model is refitted, and this is repeated until there is nothing to trim or maxit iterations are done.
return_loglik	Return the log-likelihood of the trimmed model together with the model object. The default is FALSE.
zerotol	Values smaller than this are trimmed to zero.
verbose	Print results of trimming. The default is TRUE.

simulate_hmm
--------------

Simulate hidden Markov models

# Description

Simulate sequences of observed and hidden states given parameters of a hidden Markov model.

simulate\_hmm 65

# Usage

```
simulate_hmm(n_sequences, initial_probs, transition_probs, emission_probs,
   sequence_length)
```

# **Arguments**

### Value

A list of state sequence objects of class stslist.

### See Also

build\_hmm and fit\_model for building and fitting hidden Markov models; ssplot for plotting multiple sequence data sets; seqdef for more information on state sequence objects; and simulate\_mhmm for simulating mixture hidden Markov models.

# **Examples**

```
# Parameters for the HMM
emission_probs <- matrix(c(0.5, 0.2, 0.5, 0.8), 2, 2)
transition_probs <- matrix(c(5/6, 1/6, 1/6, 5/6), 2, 2)
initial_probs <- c(1, 0)

# Setting the seed for simulation
set.seed(1)

# Simulating sequences
sim <- simulate_hmm(
    n_sequences = 10, initial_probs = initial_probs,
    transition_probs = transition_probs,
    emission_probs = emission_probs,
    sequence_length = 20)

```

simulate\_mhmm

```
simulate_initial_probs
```

Simulate Parameters of Hidden Markov Models

# **Description**

These are helper functions for quick construction of initial values for various model building functions. Mostly useful for global optimization algorithms which do not depend on initial values.

# Usage

```
simulate_initial_probs(n_states, n_clusters = 1)
simulate_transition_probs(n_states, n_clusters = 1, left_right = FALSE,
    diag_c = 0)
simulate_emission_probs(n_states, n_symbols, n_clusters = 1)
```

# **Arguments**

n\_states Number of states in each cluster.

n\_clusters Number of clusters.

left\_right Constrain the transition probabilities to upper triangular. Default is FALSE.

diag\_c A constant value to be added to diagonal of transition matrices before scaling.

n\_symbols Number of distinct symbols in each channel.

### See Also

build\_hmm, build\_mhmm, build\_mmm, build\_mmm, and build\_lcm for constructing different types of models.

simulate\_mhmm

Simulate Mixture Hidden Markov Models

# Description

Simulate sequences of observed and hidden states given the parameters of a mixture hidden Markov model.

#### Usage

```
simulate_mhmm(n_sequences, initial_probs, transition_probs, emission_probs,
  sequence_length, formula, data, coefficients)
```

simulate\_mhmm 67

# Arguments

n\_sequences The number of simulations.

initial\_probs A list containing vectors of initial state probabilities for the submodel of each

cluster.

transition\_probs

A list of matrices of transition probabilities for the submodel of each cluster.

emission\_probs A list which contains matrices of emission probabilities or a list of such objects

(one for each channel) for the submodel of each cluster. Note that the matrices must have dimensions sxm where s is the number of hidden states and m is the

number of unique symbols (observed states) in the data.

sequence\_length

The length of the simulated sequences.

formula Covariates as an object of class formula, left side omitted.

data An optional data frame, a list or an environment containing the variables in the

model. If not found in data, the variables are taken from environment(formula).

coefficients An optional kxl matrix of regression coefficients for time-constant covariates

for mixture probabilities, where l is the number of clusters and k is the number of covariates. A logit-link is used for mixture probabilities. The first column is

set to zero.

# Value

A list of state sequence objects of class stslist.

# **Description**

ssp

Function ssp defines the arguments for plotting with plot.ssp or gridplot.

### Usage

```
ssp(x, hidden.paths = NULL, plots = "obs", type = "d", tlim = 0,
sortv = NULL, sort.channel = 1, dist.method = "OM",
with.missing = FALSE, missing.color = NULL, title = NA,
title.n = TRUE, cex.title = 1, title.pos = 1,
```

```
with.legend = "auto", ncol.legend = "auto",
with.missing.legend = "auto", legend.prop = 0.3, cex.legend = 1,
hidden.states.colors = "auto", hidden.states.labels = "auto",
xaxis = TRUE, xlab = NA, xtlab = NULL, xlab.pos = 1,
ylab = "auto", hidden.states.title = "Hidden states",
yaxis = FALSE, ylab.pos = "auto", cex.lab = 1, cex.axis = 1,
withlegend, ...)
```

# **Arguments**

x Either a hidden Markov model object of class hmm or a state sequence object

of class stslist (created with the seqdef) function) or a list of state sequence

objects.

hidden.paths Output from hidden\_paths function. Optional, if x is a hmm object or if type =

"obs".

plots What to plot. One of "obs" for observations (the default), "hidden.paths" for

most probable paths of hidden states, or "both" for observations and hidden

paths together.

type The type of the plot. Available types are "I" for sequence index plots and "d"

for state distribution plots (the default). See segplot for details.

tlim Indexes of the subjects to be plotted (the default is 0, i.e. all subjects are plotted).

For example, tlim = 1:10 plots the first ten subjects in data.

sortv A sorting variable or a sort method (one of "from.start", "from.end", "mds.obs",

or "mds.hidden") for type = "I". The value "mds.hidden" is only available when hidden paths are available. Options "mds.obs" and "mds.hidden" automatically arrange the sequences according to the scores of multidimensional scaling (using cmdscale) for the observed data or hidden states paths. MDS scores are computed from distances/dissimilarities using a metric defined in argument dist.method. See plot.stslist for more details on "from.start"

and "from.end".

sort.channel The number of the channel according to which the "from.start" or "from.end" sorting is done. Sorting according to hidden states is called with value 0. The

default value is 1 (the first channel).

dist.method The metric to be used for computing the distances of the sequences if multi-

dimensional scaling is used for sorting. One of "OM" (optimal matching, the default), "LCP" (longest common prefix), "RLCP" (reversed LCP, i.e. longest common suffix), "LCS" (longest common subsequence), "HAM" (Hamming distance), and "DHD" (dynamic Hamming distance). Transition rates are used for defining substitution costs if needed. See seqdef for more information on

the metrics.

with.missing Controls whether missing states are included in state distribution plots (type =

"d"). The default is FALSE.

missing.color Alternative color for representing missing values in the sequences. By default,

this color is taken from the missing. color attribute of the sequence object.

title Main title for the graphic. The default is NA: if title.n = TRUE, only the number

of subjects is plotted. FALSE prints no title, even when title.n = TRUE.

title.n Controls whether the number of subjects (in the first channel) is printed in the title of the plot. The default is TRUE: n is plotted if title is anything but FALSE. cex.title Expansion factor for setting the size of the font for the title. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size. Controls the position of the main title of the plot. The default value is 1. Values title.pos greater than 1 will place the title higher. with.legend Defines if and where the legend for the states is plotted. The default value "auto" (equivalent to TRUE and "right") creates separate legends for each requested plot and positiones them on the right-hand side of the plot. Other possible values are "bottom", "right.combined", and "bottom.combined", of which the last two create a combined legend in the selected position. FALSE prints no legend. ncol.legend (A vector of) the number of columns for the legend(s). The default "auto" determines number of columns depending on the position of the legend. with.missing.legend If set to "auto" (the default), a legend for the missing state is added automatically if one or more of the sequences in the data/channel contains missing states and type = "I". If type = "d" missing states are omitted from the legends unless with.missing = TRUE. With the value TRUE a legend for the missing state is added in any case; equivalently FALSE omits the legend for the missing state. Sets the proportion of the graphic area used for plotting the legend when with. legend legend.prop is not FALSE. The default value is 0.3. Takes values from 0 to 1. cex.legend Expansion factor for setting the size of the font for the labels in the legend. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size. hidden.states.colors A vector of colors assigned to hidden states. The default value "auto" uses the colors assigned to the stslist object (created with segdef) if hidden.paths is given; otherwise colors from colorpalette are automatically used. hidden.states.labels Labels for the hidden states. The default value "auto" uses the names provided in x\$state\_names if x is an hmm object; otherwise the number of the hidden xaxis Controls whether an x-axis is plotted below the plot at the bottom. The default value is TRUE. xlab An optional label for the x-axis. If set to NA, no label is drawn. xtlab Optional labels for the x-axis tick labels. If unspecified, the column names of the segdata sequence object are used (see segdef). xlab.pos Controls the position of the x-axis label. The default value is 1. Values greater than 1 will place the label further away from the plot. ylab Labels for the channels shown as labels for y-axes. A vector of names for each channel (observations). The default value "auto" uses the names provided in x\$channel\_names if x is an hmm object; otherwise the names of the list in x if given, or the number of the channel if names are not given. FALSE prints no

labels.

hidden.states.	title
	Optional label for the hidden state plot (in the y-axis). The default is "Hidden states".
yaxis	Controls whether or not to plot the y-axis. The default is FALSE.
ylab.pos	Controls the position of the y axis labels (labels for channels and/or hidden states). Either "auto" or a numerical vector indicating how far away from the plots the titles are positioned. The default value "auto" positions all titles on line 1. Shorter vectors are recycled.
cex.lab	Expansion factor for setting the size of the font for the axis labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
cex.axis	Expansion factor for setting the size of the font for the x-axis tick labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.
withlegend	Deprecated. Use with.legend instead.

Other arguments to be passed on to seqplot.

### Value

Object of class ssp.

# See Also

plot.ssp for plotting objects created with the ssp function; gridplot for plotting multiple ssp objects; build\_hmm and fit\_model for building and fitting hidden Markov models; hidden\_paths for computing the most probable paths of hidden states; and biofam3c and hmm\_biofam for information on the data and model used in the example.

ssplot

Stacked Plots of Multichannel Sequences and/or Most Probable Paths from Hidden Markov Models

# **Description**

Function ssplot plots stacked sequence plots of sequence object created with the seqdef function or observations and/or most probable paths of hmm objects.

# Usage

```
ssplot(x, hidden.paths = NULL, plots = "obs", type = "d", tlim = 0,
    sortv = NULL, sort.channel = 1, dist.method = "OM",
    with.missing = FALSE, missing.color = NULL, title = NA,
    title.n = TRUE, cex.title = 1, title.pos = 1,
    with.legend = "auto", ncol.legend = "auto",
    with.missing.legend = "auto", legend.prop = 0.3, cex.legend = 1,
    hidden.states.colors = "auto", hidden.states.labels = "auto",
    xaxis = TRUE, xlab = NA, xtlab = NULL, xlab.pos = 1,
    ylab = "auto", hidden.states.title = "Hidden states",
    yaxis = FALSE, ylab.pos = "auto", cex.lab = 1, cex.axis = 1, ...)
```

### Arguments

x Either a hidden Markov model object of class hmm or a state sequence object

of class stslist (created with the seqdef) function) or a list of state sequence

objects.

hidden.paths Output from hidden\_paths function. Optional, if x is a hmm object or if type =

"obs".

plots What to plot. One of "obs" for observations (the default), "hidden.paths" for

most probable paths of hidden states, or "both" for observations and hidden

paths together.

type The type of the plot. Available types are "I" for sequence index plots and "d"

for state distribution plots (the default). See segplot for details.

tlim Indexes of the subjects to be plotted (the default is 0, i.e. all subjects are plotted).

For example, tlim = 1:10 plots the first ten subjects in data.

sortv A sorting variable or a sort method (one of "from.start", "from.end", "mds.obs",

or "mds.hidden") for type = "I". The value "mds.hidden" is only available when hidden paths are available. Options "mds.obs" and "mds.hidden" automatically arrange the sequences according to the scores of multidimensional scaling (using cmdscale) for the observed data or hidden states paths. MDS scores are computed from distances/dissimilarities using a metric defined in argument dist.method. See plot.stslist for more details on "from.start"

and "from.end".

sort.channel The number of the channel according to which the "from.start" or "from.end"

sorting is done. Sorting according to hidden states is called with value 0. The

default value is 1 (the first channel).

dist.method

The metric to be used for computing the distances of the sequences if multidimensional scaling is used for sorting. One of "OM" (optimal matching, the default), "LCP" (longest common prefix), "RLCP" (reversed LCP, i.e. longest common suffix), "LCS" (longest common subsequence), "HAM" (Hamming distance), and "DHD" (dynamic Hamming distance). Transition rates are used for defining substitution costs if needed. See seqdef for more information on the metrics.

with.missing

Controls whether missing states are included in state distribution plots (type = "d"). The default is FALSE.

missing.color

Alternative color for representing missing values in the sequences. By default, this color is taken from the missing.color attribute of the sequence object.

title

Main title for the graphic. The default is NA: if title.n = TRUE, only the number of subjects is plotted. FALSE prints no title, even when title.n = TRUE.

title.n

Controls whether the number of subjects (in the first channel) is printed in the title of the plot. The default is TRUE: n is plotted if title is anything but FALSE.

cex.title

Expansion factor for setting the size of the font for the title. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.

title.pos

Controls the position of the main title of the plot. The default value is 1. Values greater than 1 will place the title higher.

with.legend

Defines if and where the legend for the states is plotted. The default value "auto" (equivalent to TRUE and "right") creates separate legends for each requested plot and positiones them on the right-hand side of the plot. Other possible values are "bottom", "right.combined", and "bottom.combined", of which the last two create a combined legend in the selected position. FALSE prints no legend.

ncol.legend

(A vector of) the number of columns for the legend(s). The default "auto" determines number of columns depending on the position of the legend.

with.missing.legend

If set to "auto" (the default), a legend for the missing state is added automatically if one or more of the sequences in the data/channel contains missing states and type = "I". If type = "d" missing states are omitted from the legends unless with.missing = TRUE. With the value TRUE a legend for the missing state is added in any case; equivalently FALSE omits the legend for the missing state.

legend.prop

Sets the proportion of the graphic area used for plotting the legend when with. legend is not FALSE. The default value is 0.3. Takes values from 0 to 1.

cex.legend

Expansion factor for setting the size of the font for the labels in the legend. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.

hidden.states.colors

A vector of colors assigned to hidden states. The default value "auto" uses the colors assigned to the stslist object (created with seqdef) if hidden.paths is given; otherwise colors from colorpalette are automatically used.

hidden.states.labels		
	Labels for the hidden states. The default value "auto" uses the names provided in x\$state_names if x is an hmm object; otherwise the number of the hidden state.	
xaxis	Controls whether an x-axis is plotted below the plot at the bottom. The default value is TRUE.	
xlab	An optional label for the x-axis. If set to NA, no label is drawn.	
xtlab	Optional labels for the x-axis tick labels. If unspecified, the column names of the sequence object are used (see seqdef).	
xlab.pos	Controls the position of the x-axis label. The default value is 1. Values greater than 1 will place the label further away from the plot.	
ylab	Labels for the channels shown as labels for y-axes. A vector of names for each channel (observations). The default value "auto" uses the names provided in x\$channel_names if x is an hmm object; otherwise the names of the list in x if given, or the number of the channel if names are not given. FALSE prints no labels.	
hidden.states.	title	
	Optional label for the hidden state plot (in the y-axis). The default is "Hidden states".	
yaxis	Controls whether or not to plot the y-axis. The default is FALSE.	
ylab.pos	Controls the position of the y axis labels (labels for channels and/or hidden states). Either "auto" or a numerical vector indicating how far away from the plots the titles are positioned. The default value "auto" positions all titles on line 1. Shorter vectors are recycled.	
cex.lab	Expansion factor for setting the size of the font for the axis labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.	
cex.axis	Expansion factor for setting the size of the font for the x-axis tick labels. The default value is 1. Values lesser than 1 will reduce the size of the font, values greater than 1 will increase the size.	
	Other arguments to be passed on to seqplot.

summary.mhmm 77

```
title = FALSE, ylab = FALSE)
## End(Not run)
```

summary.mhmm

Summary method for mixture hidden Markov models

# **Description**

Function summary.mhmm gives a summary of a mixture hidden Markov model.

### Usage

```
## S3 method for class 'mhmm'
summary(object, parameters = FALSE,
   conditional_se = TRUE, log_space = FALSE, ...)
```

# **Arguments**

object Mixture hidden Markov model of class mhmm.

parameters Whether or not to return transition, emission, and initial probabilities. FALSE by default.

conditional\_se Return conditional standard errors of coefficients. See vcov.mhmm for details. TRUE by default.

log\_space Make computations using log-space instead of scaling for greater numerical stability at cost of decreased computational performance. Default is FALSE.

... Further arguments to vcov.mhmm.

### **Details**

The summary.mhmm function computes features from a mixture hidden Markov model and stores them as a list. A print method prints summaries of these: log-likelihood and BIC, coefficients and standard errors of covariates, means of prior cluster probabilities, and information on most probable clusters.

# Value

transition\_probs Transition probabilities. Only returned if parameters = TRUE.
emission\_probs Emission probabilities. Only returned if parameters = TRUE.
initial\_probs Initial state probabilities. Only returned if parameters = TRUE.
logLik Log-likelihood.

**BIC** Bayesian information criterion.

most\_probable\_cluster The most probable cluster according to posterior probabilities.
coefficients Coefficients of covariates.

78 trim\_model

vcov Variance-covariance matrix of coefficients.

prior\_cluster\_probabilities Prior cluster probabilities (mixing proportions) given the covariates.
posterior\_cluster\_probabilities Posterior cluster membership probabilities.
classification\_table Cluster probabilities (columns) by the most probable cluster (rows).

# See Also

build\_mhmm and fit\_model for building and fitting mixture hidden Markov models; and mhmm\_biofam for information on the model used in examples.

# **Examples**

```
# Loading mixture hidden Markov model (mhmm object)
# of the biofam data
data("mhmm_biofam")
# Model summary
summary(mhmm_biofam)
```

trim\_model

Trim Small Probabilities of Hidden Markov Model

# Description

Function trim\_model tries to set small insignificant probabilities to zero without decreasing the likelihood.

# Usage

```
trim_model(model, maxit = 0, return_loglik = FALSE, zerotol = 1e-08,
  verbose = TRUE, ...)
```

# **Arguments**

model	Model of class hmm or mhmm for which frimming is performed.
maxit	Number of iterations. After zeroing small values, the model is refitted, and this is repeated until there is nothing to trim or maxit iterations are done.
return_loglik	Return the log-likelihood of the trimmed model together with the model object. The default is FALSE.
zerotol	Values smaller than this are trimmed to zero.
verbose	Print results of trimming. The default is TRUE.
	Further parameters passed on to fit_model.

vcov.mhmm 79

### See Also

build\_hmm and fit\_model for building and fitting hidden Markov models; and hmm\_biofam for information on the model used in the example.

# **Examples**

```
data("hmm_biofam")
# Testing if changing parameter values smaller than 1e-03 to zero
# leads to improved log-likelihood.
hmm_trim <- trim_model(hmm_biofam, zerotol = 1e-03, maxit = 10)</pre>
```

vcov.mhmm

Variance-Covariance Matrix for Coefficients of Covariates of Mixture Hidden Markov Model

# **Description**

Returns the asymptotic covariances matrix of maximum likelihood estimates of the coefficients corresponding to the explanatory variables of the model.

# Usage

```
## S3 method for class 'mhmm'
vcov(object, conditional = TRUE, threads = 1,
  log_space = FALSE, ...)
```

# **Arguments**

object Object of class mhmm.

conditional If TRUE (default), the standard errors are computed conditional on other model

parameters. See details.

threads Number of threads to use in parallel computing. Default is 1.

log\_space Make computations using log-space instead of scaling for greater numerical sta-

bility at cost of decreased computational performance. Default is FALSE.

... Additional arguments to function jacobian of numDeriv package.

### Details

The conditional standard errors are computed using analytical formulas by assuming that the coefficient estimates are not correlated with other model parameter estimates (or that the other parameters are assumed to be fixed). This often underestimates the true standard errors, but is substantially faster approach for preliminary analysis. The non-conditional standard errors are based on the numerical approximation of the full Hessian of the coefficients and the model parameters corresponding to nonzero probabilities. Computing the non-conditional standard errors can be slow for large models as the Jacobian of analytical gradients is computed using finite difference approximation.

80 vcov.mhmm

# Value

Matrix containing the variance-covariance matrix of coefficients.
